LIST OF ILLUSTRATIONS

SPECIAL PLATES

	PAGE
Bronchiectasis, Disappearance of and Re-expansion of Atelectatic Lower Lobe (G. H. Jennings)	facing 979
Calcinosis, a Case of (A. J. Cloveland and A. P. Agnew)	facing 27
Cancer of Breast, Conservative Treatment of (Geoffrey Keynes)	inset between 666 and 667
Carcinoma of Stomach (John Morley)	facing 978
—— of Ureter (Alexander Lyall)	facing 978
Coronary Thrombosis, Fatal, in a Man Aged 23 (John R. Blazé)	facing 27
Craniocleidodysostosis (Léon Feinson Muldavin)	inset between 26 and 27
Gaucher's Disease of the Lungs (Bernard Myers)	inset between 26 and 27
Haemorrhage, Spontaneous Subarachnoid (Abdulla Karmally and K. D. Manohar)	facing 979
Leukaemia, Chronic Monocytic (G. Stewart Smith)	facing 26
Menstruation, temporary postponement of by Oestradiol Benzoate (George L. Foss)	facing 27
Molluscum Fibrosum or Diffuse Fibromatosis (R. R. Murray)	inset between 978 and 979
Oedema, Cerebral, in Certain Mental Disorders (C. Lovell)	facing 667
Omentum, Great, Acute Torsion of (J. S. Manson)	inset between 978 and 979
Pneumonia, Disseminated Focal (J. G. Scadding)	inset between 978 and 979
Schamberg's Disease (R. A. Desai)	inset between 26 and 27
Tubo-uterine Implantation for Sterility (V. B. Green-Armytage)	inset between 26 and 27
Tumours of Bone (J. S. Young)	facing 666
Varix of Neck (H. S. Barber)	inset between 978 and 979
Vesical Extroversion with Control of Micturition (A. Ralph Thompson)	facing 26

ILLUSTRATIONS IN THE TEXT

	PAGE
Anaesthesia: Apparatus and Equipment (J. K. Hasler)	921
—— Risks of (M. D. Nosworthy)	866
Anaesthetic Apparatus, Attachment for	1025
Analgesia in Midwifery (R. J. Minnett)	539
Biliary Drainage, Continuous (Malcolm H. V. Cameron)	17
Bladder Drainage, Apparatus for	1073
Breech Delivery, Critical Survey of 349 Cases (C. H. G. Macafee and H. I. McClure)	1114
"Buttonholed" extensor expansion (D. L. C. Bingham and E. A. Jack)	701
Carcinoma of Stomach (John Morley)	950
Carpal Excisions, Extension in	377
—— Scaphoid, Union of (by Immobilization) after Six Weeks' Delay in Treatment (R. Salisbury Woods)	1119
Cataract Extraction during Narcosis (Basil Graves)	319
Climacteric, Female, Treatment of by Follicular Hormone (H. R. Donald)	903
Convergiometer for Ocular Headache (D. Stenhouse Stewart)	60
Cripples Training College, Stanmore	129
Diet in Relation to Health (J. R. Mutch and H. D. Griffith)	567
Ear Syringe and Trough, Improved	1226
Emphysema, Subcutaneous, Arising During Labour (F. H. Nussbaum)	1169
Enterotome, Non-projecting	1025
Eye Bath, Irise	1173
Flusterer's Needle, modified	706
Forceps for Introducing Suprapubic Tube	168
—— Reversible Pelvic Curve	531
Frontal Lobes in Man, Removal of (Geoffrey Jefferson)	202
Gag, Modified Boyle-Davis	751
Glossectomy, Partial, as cure of Stuttering	1239
Granulosis Rubra Nasi in Mother and Daughter (F. F. Hellier)	1068
Headlight, an Improved	68
Heart Failure, Treatment of (Crighton Bramwell)	1005
Hereditary Sebaceous Cysts (Emily A. C. Wilson)	185
Jowers, Reginald Francis	357
Lang, William	189
Lungs, Cheap Device for Postural Drainage of	584
Lymphangioplasty—the Fate of Silk (Harold Hartley and R. A. Kemp Harper)	1067
Maclaren, Norman	396
Moore, Sir John William	831
Myles, Sir Thomas	188
Needle Holder for Thoracocentesis	531
Negative Pressure Apparatus, Portable Continuous (M. J. Bennett-Jones)	613
Northern Ireland, Views of	76, 77
Nuttall, George Henry Falkiner	1308
Oxygen tent, "home-made"	391
Pubertas Praecox, Case of (W. L. Kerr)	620
Pulp-space Infection (James Hardman)	157
Radium Policy and Practice	1200
Rambaut, Daniel Frederick	1201
Rectum, Foreign Body in	638
Royal College of Surgeons of England with the Bernhard Baron Laboratories	1187
Sedimentometer, Multiple	857
Sex Glands (E. C. Dodds)	163
"Shields" to Prevent Contamination in Gastro-Intestinal surgery	1226
Simmons, George H.	602
Smith, Edwin	356
Stomach, Multiple Foreign Bodies in (R. de Soldenhoff)	910
Suprapubic Box	664
Syringe, Higginson's	58
—— for Intravenous Injection	531
Table, Simple Traction, for Hip-Nailing Operations	751
Teratoma, Nasopharyngeal (J. Stokoe)	910
Thompson, John Gordon	394
Thomson-Walker, Sir John	779
Thoracoplasty with Extrafascial Apicolysis (Carl Semb)	651
Thrombosis Complicating Hyperthyroidism (Douglas E. Finlay)	966
Trocar and Cannula for Closed Drainage of Chest	624
Tubo-uterine Implantation for Sterility (V. B. Green-Armytage)	6
Ulcer and Carcinoma, Site of (John Morley)	314
Visceral Pain (John Morley)	1272
Volkmann's ischaemic contracture, an unusual cause of (Gawad Hamada)	418
Warts, Plantar, Instruments for	119
Wright, William	881

INDEX TO VOLUME II FOR 1937

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate headings—*for example*, Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Carcinoma; Child and Infant; Goitre, and Thyroid. Subjects dealt with under various main headings in the JOURNAL have been set out in alphabetical order under their respective headings—*for example*, "Annotations," "Correspondence," "Leading Articles," "Obituary," "Reviews," etc. Original Articles are indicated by the letter (O).

A

Aberdeen. See Scotland

Abortion, contagious, eradication of in Norway, 863
—— habitual (Percy Malpas), 230
—— —— vitamin E in treatment of (David Currie), 281, 1218 (O)
—— indications for induction of, 635, 673, 725, 775, 826, 880, 940, 997
—— medico-legal aspects of, 1192
—— missed, pregnancy test in, 358
—— review of book on, 967

ABRAHAM, J. Johnston: 99 *Wimpole Street*, rev., 1225

ABRAHAMS, Adolphe: National physical training, 990

Abscess of lung (L. S. T. Burrell), 332, 789 (O)—Correspondence on, 939

Abyssinian refugees in Kenya (parliamentary note), 1001

ACADEMY, ROYAL, OF MEDICINE IN IRELAND:
Annual general meeting, 933
Section of *Medicine*.—Demonstration of cases, 991; Contagious, 1041
[illegible]
metrium, 992

Accidents in coal mines: Numbers of boys killed and
[illegible]
——
—— motor, and alcohol, 535
—— rehabilitation after (parliamentary note), 250—Committee on, 1299
—— road: an international analysis, 806
—— —— number attributed to effects of drugs and alcohol (parliamentary note), 303
Accommodation, the mechanism of, 328
ACOMB, L. E.: Cardiac pain in gall-bladder subjects, 278
Adair, Robin and John, 1283
ADAM, Prof.: Study for foreigners in Germany, 544
—— James: Ionization for hay fever, 88, 294
ADAMS, A. Wilfrid: Treatment of club-foot, 680

Alum precipitated toxoid with anti-diphtheritic serum, 642
American Anthropologist, July-September issue, contains article on scientific influence of Sir Grafton Elliot Smith, 1258
—— field dressing station seventy-five years ago, 346
—— *Journal of Public Health*: "Sir Robert Philip, World benefactor," 1252
—— —— *of Surgery*, October, issue contains article on leading medical journals, 1258
—— medicine, review of books on, 582
Anaemia of hepatic cirrhosis, 628, 724
—— hypochromic, iron therapy in (J. F. Brock), 232
—— pernicious, with diabetes mellitus (H. G. McGregor), 617 (O)—Correspondence on, 723, 777, 829
—— repair of, 123
Anaesthesia: apparatus and equipment (J. K. Hasler), 921
—— basal, for short operations (J. H. T. Challis), 386
—— depth of for various operations (C. Langton Hewer), 330
—— endotracheal (Ivor Lewis), 630—Correspondence on, 678, 724, 775, 826
—— general, in dentistry (W. S. McConnell), 591

ANAESTHESIA IN GENERAL PRACTICE:
Anaesthesia: apparatus and equipment (J. K. Hasler), 921
—— basal, for short operations (J. H. T. Challis), 386
—— depth of for various operations (C. Langton Hewer), 330
—— endotracheal (Ivor Lewis), 630—Correspondence on, 678, 724, 775, 826
—— general, in dentistry (W. S. McConnell), 591
—— —— stages and signs of (C. Langton Hewer), 274
—— and the law (D. Harcourt Kitchin), 976—Correspondence on, 1143
—— local (C. W. Morris), 427
—— notes on physiology and pharmacology of (H. W. Featherstone), 224
—— pre-operative treatment and premedication (R. Machray), 713
—— post-operative treatment (R. Machray), 758
—— recent advances in (J. Blomfield), 175—Correspondence on, 355, 432
—— risks of (M. D. Nosworthy), 809, 865—Correspondence on, 937, 995
—— spinal (H. K. Ashworth), 671—Correspondence on, 723, 775, 826, 879, 937, 995, 1143, 1249—Note on, 782
Anaesthetic, choice of in general practice (Helen Lukis), 126—Correspondence on, 243, 302
Analgesia in midwifery (R. J. Minnitt), 537
Note on, 124

Anaesthesia, general, stages and signs of (C. Langton Hewer), 274
—— and law (D. Harcourt Kitchin), 976—Correspondence on, 1143
—— local (C. W. Morris), 427
[illegible] T. [illegible]), 335, 1269 (O)
[illegible] harmacology of
[illegible] 095
[illegible] Machray), 758
[illegible] medication (R. Machray), 713
—— recent advances in (J. Blomfield), 175—Correspondence on, 355, 432

Anaesthesia, risks of (M. D. Nosworthy), 809, 865—Correspondence on, 937, 995
—— —— of explosion in, 383
—— spinal (H. K. Ashworth), 671—Correspondence on, 723, 775, 826, 879, 937, 995, 1143, 1249—Note on, 782
—— —— for Caesarean section, 723, 775, 826, 879, 937, 995, 1143, 1250
Anaesthetic apparatus, attachment for, 1025—Correspondence on, 1095
—— choice of in general practice (Helen Lukis), 126; Correspondence on, 243, 302
Anaesthetics, information concerning diploma in, 508
—— review of book on, 969
Analgesia in midwifery (R. J Minnitt), 537
Anaphylaxis, histamine in, 186
Anastil and anastil forte, 802
Anatomical nomenclature, review of book on, 855
Anatomy Acts, Northumberland County Council and (parliamentary note), 1149
—— review of books on, 420, 913, 1278

THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION

EPITOME

OF

CURRENT MEDICAL LITERATURE

JULY TO DECEMBER, 1937

LONDON

Published at the Office of The British Medical Association, Tavistock Square, W.C.1, and
Printed by Eyre & Spottiswoode, Ltd., East Harding Street, E.C.4.

INDEX TO THE EPITOME FOR VOLUME II, 1937

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Carcinoma; Epithelioma, Malignant Disease, New Growth, Sarcoma, etc.; Child and Infant; Bronchocele, Goitre, and Thyroid; Diabetes, Glycosuria, and Sugar; Eye, Ophthalmia, and Vision, etc.

The Figures in this Index refer to the Number of the Paragraph, NOT the Page.

A

ABDELIOOS: Pyosalpinx strangulated in a hernia, 448

BRONCHOSPASM AND ASTHMA

A booklet surveying this subject, which includes diagrams and illustrations, has recently been published and has been sent to all members of the Medical Profession. You are invited to send for a copy should this have failed to reach you.

"THE LANCET" writes (28/4/34, p. 929):—

"We have received a pamphlet on 'Bronchospasm and Asthma,' written to bring before the medical profession the value of Felsol in the treatment of asthmatic subjects. The powders can be prescribed by the medical man in accordance with the definite regime which he decides to adopt in the treatment of a case, the claim for felsol being that its administration relieves promptly the attack of asthma by its influence over bronchial spasm, so that only the most severe cases would require the injection of morphia."

SHOP WINDOWS

Who is not tempted to glance at the goods displayed in the shop windows which brighten the streets of every town? The subtle attraction of articles thus brought to notice cannot be explained by any immediate need to purchase. Indeed, the majority of the contents of shop windows have no immediate appeal. They are seen and a mental note is made which may well prove useful later on.

So it is with the advertisements in the *British Medical Journal*. Sometimes, it is true, the reader searches these pages to find a particular preparation or appliance for use in the treatment of a specific case. More often the advertised products are noticed and remembered pending their being required at some future time.

In this way an up-to-date knowledge of proprietary aids to medical practice can be maintained without expense and with very little expenditure of time.

Two helpful suggestions: Pages may be cut out and filed for future reference, and it is always worth while to mention the B.M.J. when writing to advertisers.

New Books and New Editions

★

A Manual of PRACTICAL ANATOMY

A Practical Dissection Guide by Prof. J. E. FRAZER and R. H. ROBBINS designed to provide the student with all that he requires, while omitting all that is superfluous. The new Birmingham Terminology is used throughout, with a glossary of equivalent B.N.A. and O.T. terms, and the whole subject is covered in two handy volumes, each separately indexed and fully illustrated with both coloured and black-and-white drawings, at a total cost of 21 shillings.

Vol. I. Upper Limb, Lower Limb and Abdomen. 282 illustrations.
Vol. II. Thorax, Head and Neck, Central Nervous System, etc. 230 illustrations.
Price of each volume 10s. 6d. Postage 6d. each. Abroad 1s.

Modern Dietary Treatment

By M. ABRAHAMS, M.A., M.Sc., and E. M. WIDDOWSON, B.Sc., Ph.D.

"This book can be strongly recommended to medical practitioners and students, nurses and hospital dietitians. There is no other small handbook in the English language with so much accurate information about diets and so little verbiage . . . essentially practical, sober and up to date . . . should be able to look forward to a long life of usefulness."—British Medical Journal. Pp. x+328, including 60 pages of tables.
Price 8s. 6d. Postage 6d. Abroad 1s.

Minor Maladies

By LEONARD WILLIAMS, M.D.

A revised seventh edition is now ready of this well-known and well-beloved book. "One reads on with relish and profit, such as one rarely receives from the reading of a medical book. The practitioner will find here a rich mine of useful practice, as well as food for thought in every chapter . . . provides a revelation of a world of medical knowledge and experience that hospital life gives us no hint of."—Birmingham Medical Review. Seventh Edition. Pp. xii+436. Price 10s. 6d. Postage 6d. Abroad 1s.

Clinical Roentgenology of the Cardiovascular System

A new work for the Radiologist, the Cardiologist, and the general practitioner, by HUGO ROESLER, M.D. It covers the anatomy, physiology and pathology of the cardiovascular system and gives the clinical applications of the roentgen ray in cases of cardiac disorder. The book is very fully illustrated and each illustration is very closely analysed. The clinical findings in the case depicted are also given, together with the electro-cardiographic and P.M. reports when available. A most useful and important book. Pp. xvi + 344 with 199 illustrations. Price 34s. Postage 8d. Abroad 1s. 3d

BUCHANAN'S Manual of Anatomy

The new edition of this standard textbook has been revised throughout by Professor J. E. FRAZER, D.Sc. F.R.C.S., and has indeed been very largely rewritten. The regional method has been retained as the most convenient for the student and the new Birmingham Revision has been used for the first time. 230 new illustrations have been added. "It would be difficult to praise this work too highly. Seldom have we seen such a wealth of facts presented in such perfect English. The illustrations are numerous and very clear, colour being freely employed."—Medical Press and Circular. Sixth Edition. Pp. x+1,872, with 1,041 illustrations. Price 35s. Postage 9d. Abroad 2s. 4d.

7 & 8, Henrietta Street, W.C. 2

J. & A. CHURCHILL LTD.

New (2nd) Edition. 12 Plates (8 Coloured) and 60 Text-figures 21s.

DISORDERS OF THE BLOOD

L. E. H. WHITBY, C.V.O., M.C., M.D., F.R.C.P., D.P.H. *By* **C. J. C. BRITTON, M.D., D.P.H.**

Assistant Pathologist, The Middlesex Hospital. *&* Assistant Pathologist, The Middlesex Hospital.

"This extremely well-illustrated volume . . . contains the results of much experience."—THE PRACTITIONER.

Just Published. 29 Illustrations. 12s. 6d.

RECENT ADVANCES IN INDUSTRIAL HYGIENE AND MEDICINE

By T. M. LING, B.M., M.R.C.P., Member of the Medical Advisory Committee, Industrial Welfare Society. With a Foreword by J. A. NIXON, *C.M.G.*, M.D., F.R.C.P., Emeritus Professor of Medicine, University of Bristol.

"As a compendium of all the latest work Dr. Ling's book will recommend itself to all medical practitioners."—THE FOREWORD.

SEVEN OF "THE EMPIRE SERIES"

MEDICAL EMERGENCIES

By SIR LEONARD ROGERS, *K.C.S.I.*, M.D., F.R.C.P., F.R.C.S., F.R.S., late Medical Adviser, India Office, and SIR J. W. D. MEGAW, *K.C.I.E.*, M.B., B.Ch., Medical Adviser, India Office. *2nd Edition.* 2 Col. Plates and 82 Text-figures. 15s.

THE PRACTICE OF REFRACTION
By SIR STEWART DUKE-ELDER, M.D., F.R.C.S., Ophthalmic Surgeon and Lecturer in Ophthalmology, St. George's Hospital, London. *2nd Edition* 180 Illustrations. 12s. 6d.

SEVEN OF "THE RECENT ADVANCES SERIES"

ORTHOPAEDIC SURGERY
By B. H. BURNS, B.Ch., F.R.C.S., Orthopaedic Surgeon, St. George's Hospital; and V. H. ELLIS, B.Ch., F.R.C.S. Orthopaedic Surgeon, St. Mary's Hospital, London. 108 Illustrations. 15s.

ANAESTHESIA AND ANALGESIA (including Oxygen Therapy)
By C. LANGTON HEWER, M.B., B.S., D.A. (R.C.P. & S.), *Anaesthetist and Demonstrator of Anaesthetics*, St. Bartholomew's Hospital. *New (2nd) Edition.* 113 Illustrations. 15s.

DERMATOLOGY
By W. NOEL GOLDSMITH, M.D., M.R.C.P., Physician, St. John's Hospital for Diseases of the Skin, London. 8 Coloured Plates and 50 Text-figures. 18s.

ALLERGY (Asthma, Hay-Fever, Eczema, Migraine, etc.)
By G. W. BRAY, M.B., M.R.C.P., Physician in Charge of Children's Department, Prince of Wales Hospital. *3rd Edition.* 107 Illustrations, including 4 Coloured Plates. 15s.

ENDOCRINOLOGY
By A. T. CAMERON, D.Sc., F.I.C., F.R.S.C., Professor of Biochemistry, Faculty of Medicine, University of Manitoba. *3rd Edition.* 65 Figures, including 3 plates. 15s.

GENITO-URINARY SURGERY
By HAMILTON BAILEY, F.R.C.S., Surgeon, Royal Northern Hospital; and N. M. MATHESON, M.B., F.R.C.S., Surgeon, Central Middlesex County Hospital. *89 Illustrations* 15s.

RADIOLOGY
By PETER KERLEY, M.D., B.Ch., D.M.R.E., Assistant Radiologist, Westminster Hospital. *2nd Edition.* 176 Illustrations. 15s.

Visitors welcomed to our Stand No. 36 at B.M.A. Exhibition, Belfast.

104 GLOUCESTER PLACE LONDON W.1

ARNOLD BOOKS

A Valuable Guide for Practitioners

PRE-NATAL AND POST-NATAL MANAGEMENT

By J. ST. GEORGE WILSON, M.B., Ch.M., F.R.C.S., F.C.O.G., Hon. Obstetric Surgeon to the Royal Infirmary, Consulting Obstetrician to the Walton Hospital, and Lecturer in the University, Liverpool. With a Foreword by Sir COMYNS BERKELEY. viii + 224 pages, 80 Illustrations. 10s. 6d. net.

Mr. Wilson deprecates undue interference, and thinks too little regard is often paid to the general systemic condition. He describes in a practical manner the management of normal and abnormal pregnancies, including useful chapters on X-rays, contraception and sterilisation.

TOPLEY & WILSON'S PRINCIPLES OF BACTERIOLOGY AND IMMUNITY

Second Edition. One Volume. Super Royal 8vo. xvi + 1645 pages. 276 Illustrations. 192 Tables. 50s. net.

"It has already become a classic . . . as a book for the advanced student it is unrivalled by any other work. It is rare to find the functions of a reference book and a text-book so admirably combined."—*The Lancet.*

HUTCHISON'S LECTURES ON DISEASES OF CHILDREN

Seventh Edition. viii + 452 pages. 106 Illustrations. 21s. net.

"There are many good text-books on paediatrics, but we do not know any one which achieves so well this purpose of a general and practical introduction to the subject."—*Brit. Med. Jnl.*

New (Eighth) Edition, fully Revised

THE DIAGNOSIS OF NERVOUS DISEASES

By SIR JAMES PURVES-STEWART, K.C.M.G., C.B., M.D., F.R.C.P., Consulting Physician to the Westminster Hospital. viii + 843 pages. 337 Illustrations. 35s. net.

For the new edition of this well-known book it has been necessary to increase the length by nearly 100 pages in order to include the results of recent research. The whole of the text has been revised, with many new diagrams.

GARROD, BATTEN & THURSFIELD'S DISEASES OF CHILDREN

Third Edition. With 36 contributors. Edited by HUGH THURSFIELD and DONALD PATERSON, Physicians to the Hospital for Sick Children, London. xii + 1152 pages, with 2 Coloured Plates and 277 Illustrations. 50s. net.

"For the editors, the book must be regarded as a triumph. It contains that body of knowledge of children's diseases which will endure, even though as time passes it becomes incomplete."—*British Medical Journal.*

WILLIAM BROWN'S PSYCHOLOGY & PSYCHOTHERAPY

Third Edition. viii + 256 pages. 12s. 6d. net.

"It is a very readable mixture of theory and practice, the more so since the author has drawn freely on his great experience as a psychotherapist and as a lecturer."—*Clinical Journal.*

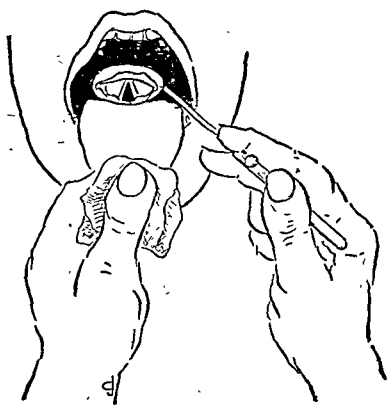
NEW!—Diseases of the Larynx

By Drs. CHEVALIER JACKSON and CHEVALIER L. JACKSON



HOW THIS NEW BOOK MEETS YOUR NEEDS

Just Ready! Family Physician, Surgeon, Laryngologist and other Specialists have enthusiastically welcomed this *new book* because of the clinical help it gives them in the treatment of diseases of the larynx.

The work is a clinical record of the large laryngeal practice of Drs. Chevalier and Chevalier L. Jackson. It is *not* a restating of literature already existing. This work is *new* in the strictest sense of that word—new and original in text and illustration.

Treatment. The treatments presented in this book are those that are being used by the authors themselves. They are sound, helpful, and include both operative and non-operative measures. You are told what therapy to use, when to use it and how to use it. You are told when and how to use local applications, solutions, vaccines, etc. You are given help on questions of climate, rest, avoidance of irritation. Operative procedures and medical treatments are thoroughly covered in step-by-step technique with illustrations. You are given indications for each procedure, modifications for special conditions, management of complications, after-care, how to avoid pitfalls, and even nursing care. There are 44 *pages on Acute and Chronic Laryngitis*, 40 pages on Cancer, detailed chapters on Intubation, Tracheotomy, etc.

ONE OF 221 FINE ILLUSTRATIONS

MIRROR LARYNGOSCOPY

Brush sketch showing position of mirror and examiner's hands during mirror laryngoscopy. The tongue is held forward over *left index-finger, by-thumb and-index, with* a folded piece of gauze for better security of grip as well as to protect examiner from *infective secretions.* Mirror is held in right hand; it is round but appears ellipsoid due to foreshortening. It is important to remember that the laryngeal image is distorted by this same foreshortening but not quite to the same extent; its apparent *anteroposterior* diameter is lessened.

Diagnosis. The technique of examination is precisely described and illustrated, including mirror and direct laryngoscopy, palpation, X-ray examination, examination of nasal chambers, sinuses, teeth and ears. There is specific help on differential diagnosis. For example, you are shown the importance of *Hoarseness*, both in adults and children; and you are given a list of the many diseases and conditions with which this common symptom may be associated. You are given 11 "axioms" of things to do and not to do in diagnosing laryngeal disease. Then under each disease diagnostic signs are described in detail. You are given laryngeal symptoms of diseases of other parts of the body as well as remote symptoms of laryngeal disease.

The Illustrations. There are 221 of them, showing *living pathology*, procedures and technique. There are 11 plates of life-like drawings in colours. These illustrations are the work of Dr. Chevalier Jackson himself.

PARTIAL CONTENTS

Anatomy and Physiology.

Examination.

Ætiology, Symptomatology, Diagnosis and General Discussion of Treatment, *including list of diseases in which hoarseness is a symptom.*

Diseases and Injuries of Larynx, *including 44 pages on acute, specific, non-specific and chronic laryngitis in adults and children*

Laryngeal Diseases Accompanying General Diseases, *such as dermatoses, exanthemata, endocrine disturbances, diphtheria, etc.*

Neuroses and Neuronoses of Larynx, *including sensory and motor affections in adults and children.*

Innervation Disorders, *including cough, voice and speech defects.*

Benign, Borderline and Malignant Tumours, *including 40 pages on cancer.*

Endolaryngeal Procedures and Operations.

External Operations for Laryngeal Stenosis.

Operations for Malignancy.

The Larynx and its Diseases. By CHEVALIER JACKSON, M.D., Sc.D., LL.D., F.A.C.S., Professor of Broncho-scopy and Esophago-scopy; and CHEVALIER L. JACKSON, A.B., M.D., M.Sc. (Med.), F.A.C.S., Professor of Clinical Broncho-scopy and Esophago-scopy, Temple University, Philadelphia. Octavo of 555 pages, with *221 illustrations and 11 plates in colours.* Cloth, 35s. net.

In acting as an executor or trustee, the Westminster Bank aims at putting itself in the position of a private trustee. It is therefore its practice to employ the family solicitor, if there is one, or any other solicitor the client may name; by such means the Bank succeeds in combining domestic tradition with business efficiency. A book showing the advantages of corporate executorship and the terms of appointment may be had at any branch or at the branch situated in B. M. A. House, Tavistock Square, W.C.1

Why two packets?

Not noticing the difference you may ask this question, and if you are looking for a good very mild Cigarette —we hope you will—because one packet holds the old favourite Player's "Medium" and the other Player's "Mild." This old established brand, although not so well known as the famous "Medium," is also blended from selected Virginia leaf only, producing a Cigarette mild but thoroughly satisfying. Both brands are Plain and Cork Tipped—"Medium" in blue lettered packets, "Mild" red lettering —but remember "Medium" or "Mild" —It's the Tobacco that Counts.

THE FILTER TIP WILL KEEP THEM FIT

Because of its double function, the "du Maurier" filter tip has become a really important factor to smokers—specially to those with a tendency to sensitive throat. Each "du Maurier" has a five layer filter made up of pure white vegetable tissue interleaved with cellulose fibre. The filter allows no bits in the mouth and isolates all irritants. This filter is a feature on *both* the plain tip 'medium' and the cork tip.

ANNOUNCING PHILIPS

BIOSOL

ONE LAMP BUT A CHOICE OF 2 WAVE-BANDS!

STUDY THESE ADVANTAGES

- ★ Two wave-bands: From 4350—1850 A.U. or with 'Dorno' filter: From 4350—2900 A.U.
- ★ Self-starting electronic discharge burner — long life — requires no tilting—quickly reaches full intensity.
- ★ Highly efficient reflector system intensifies output threefold.
- ★ Lamp can be used directly over patient ensuring accurate dosage in full body treatments.
- ★ Complete electrical safety — shockproof construction throughout.
- ★ Mechanical features simple and effective—lamp adjustable for height and angle.
- ★ Economical to run due to low current consumption in relation to ultra-violet output.
- ★ Generates sufficient heat to keep patient comfortably warm during treatment.
- ★ Occupies very little floor space and easily moved when required.
- ★ Combines maximum efficiency and convenience with an attractive appearance and superb finish.

Mild Constipation shown to yield to laxative effect of HOVIS

Many of the mild forms of constipation so prevalent to-day are attributed to the consumption of foods deficient in Vitamin 'B.' In comparing the effects of various kinds of bread it is seen that HOVIS germ bread is superior to either white bread or wholemeal in supplying this deficiency.

Whilst white bread contains practically no Vitamin 'B,' HOVIS, with its added proportion of 25% wheat-germ, supplies an abundance of this essential food-element. Unlike wholemeal bread, HOVIS contains only a minute percentage of bran and indigestible cellulose. In other words its incorporation in the normal diet ensures not only a higher standard of nutrition but easier assimilation and regular evacuation of the intestinal contents.

VITAMIN 'B' CONTENT ACTS AS AID TO REGULARITY

Modern Iron Therapy

Iron 'Jelloids' are an elegant and reliable means of administering the protocarbonate of iron. The preparation has none of the disadvantages of Pil. Blaud. The iron content remains fresh and unoxidized indefinitely, and injury to the teeth is avoided.

The 'Jelloids' are highly effective in the treatment of achlorhydric anæmia and indeed in all the simple anæmias in which massive iron therapy is indicated.

Iron Jelloids

You are cordially invited to apply for samples for clinical test.
The Iron 'Jelloid' Co. Ltd., King George's Avenue, Watford, Herts.

THE IDEAL ANTACID

Magnoleum is an emulsion of liquid paraffin and magnesium hydroxide prepared entirely by mechanical means without the aid of any constipating mucilaginous emulsifying agents. Its action is that of its active ingredients in an extremely fine state of sub-division. Being perfectly miscible with water or milk it may be diluted before taking, given to bottle-fed infants in food, etc. It is readily acceptable to children and delicate or fastidious adults.

Issued in convenient wide mouthed glass bottles, 1/3 and 2/6. Write for specimen for clinical trial.

KERFOOT

MAGNOLEUM STOMACH CORRECTIVE

Made in England by THOMAS KERFOOT & CO. LTD., Vale of Bardsley, Lancashire.

LACTAGOL (Edestine, Calcium, Phosphorus) helps to compensate for the constant drain by the foetus upon the reserves of the expectant mother.
It is a valuable roborant during convalescence following parturition and exerts a definite galactagoguic action on the mammary glands of the nursing mother.
Specimens for clinical trial free on application. Lactagol Ltd., Mitcham, Surrey.

"CALCYDIC" calcium vitamin D granules

Supplies of calcium and phosphorus are essential to the action of vitamin D. Whereas ordinary calcium phosphate contains 1 part by weight of phosphorus to 2 of calcium, dicalcium phosphate ($CaHPO_4$) contains 3 parts of phosphorus to 4 of calcium. "Calcydic" Granules are delicious.

Each teaspoonful contains—

Dicalcium phosphate	7½ grains
Vitamin D	1,500 units
Glucose, Chocolate and Cane Sugar	

These granules may be given to children or adults, prophylactically or therapeutically, in rickets, pregnancy, lactation, osteomalacia, menorrhagia, convalescence, chilblains, and urticaria.

In Tins of ½ lb. 2/3, and 1 lb. 4/-

OVALTINE

AN AID TO HEALTHY DEVELOPMENT

MODERN medical research makes it increasingly clear that abnormalities of form, mental defects and even permanent constitutional weakness, are often a direct result of failure to obtain in infancy a diet adequate to the physiological needs of the organism. The basic necessity, therefore, in constructing the dietary of the infant and growing child, is to ensure one that is complete in all the essential food elements.

"Ovaltine" finds one of its most valuable applications in this direction. Composed of the nutritive constituents of fresh, full-cream milk, eggs and malt, in well-balanced proportions, it supplies calcium, phosphorus, vitamins and other accessory food factors, and its regular addition to the ordinary diet of the child renders this safe and adequate.

"Ovaltine" is so delicious and easily digested that it can be prescribed with complete confidence for children of all ages. "Ovaltine" is easily prepared and is most economical.

A liberal supply for clinical trial sent free on request.

MB/S/22

A major operation in progress in the operating theatre of a London Hospital.

DEGREES OF PROTECTION....

THE most elaborate precautions against every possible chance of germ infection are of course essential in the operating theatre. It would be ridiculous, however, to expect anything approaching this meticulous attention to antiseptic cleanliness in everyday hygiene and in the home treatment of superficial wounds.

The general public is nevertheless beginning to realise the importance of germ-free cleanliness. Hygienic standards to-day are higher than they have ever been. It is generally agreed by medical men that although regular use of antiseptics is not desirable or really necessary for ordinary toilet purposes, the use of a reliable antiseptic soap can play a very valuable part in the prevention of infectious disease. Face and hands are continually exposed to infectious germs, and require washing with Wright's Coal Tar Soap.

Wright's has substantial antiseptic and antipruritic qualities. For over 70 years it has enjoyed the confidence of the medical profession, and to-day more doctors use Wright's than any other brand of toilet soap. Wright's Coal Tar Soap is prepared from materials selected after stringent tests. It is the only soap in the world to contain 'liquor carbonis detergens' (Wright's), the valuable dermatological therapeutic recommended by skin specialists the world over. In surgeries, hospitals, nursing homes and private households Wright's meets all the requirements of modern everyday hygiene. You can use it and recommend it to your patients with complete confidence.

Cystopurin

The ideal urinary antiseptic for oral administration!

1 Produces no gastric irritation or toxic symptoms.

2 Is readily absorbed from the gut and excreted in the urine.

3 Causes no renal irritation.

4 Renders the urine bactericidal in low concentrations.

5 Acts from the renal pelvis downwards.

6 Is active in either acid or alkaline urine.

7 Perfectly safe for use in febrile conditions.

8 Acts on all causative organisms of urinary infections.

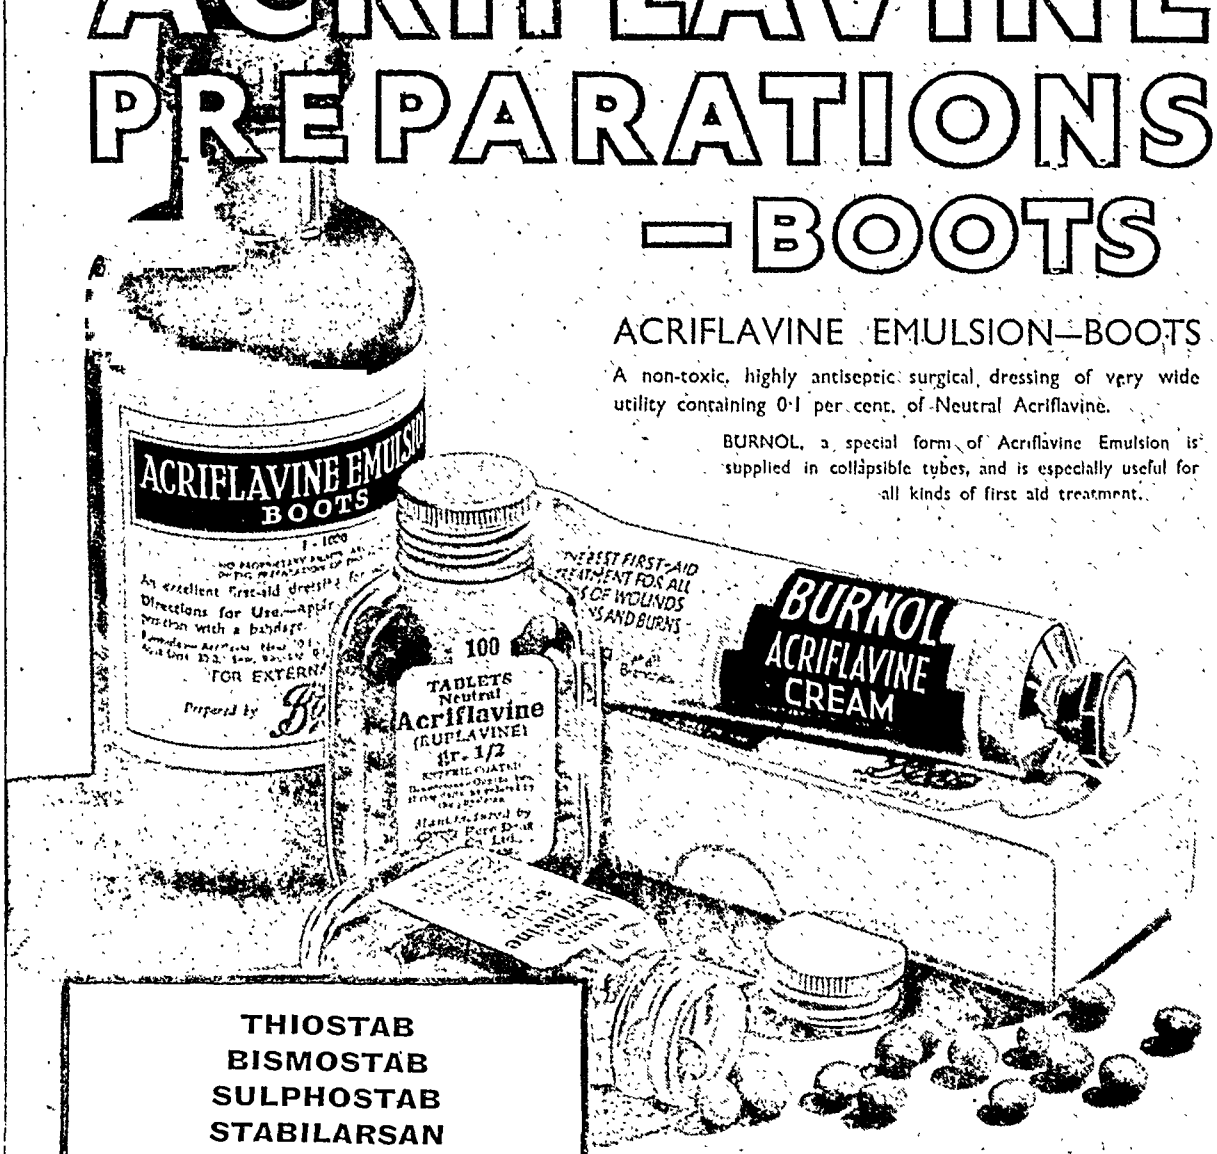
CYSTITIS

From information received :—

"The patient was myself, aged 66 years. Owing to the cold severe weather I had contracted a semi-acute attack of cystitis with strangury, frequency of micturition, inability to retain urine in bladder, urine full of muco-pus and alkaline in reaction. I took two tablets of Cystopurin in a tumbler of water three times a day, and in 24 hours the pain and frequency were relieved. In 48 hours the urine was clear and normal in reaction."

"I find that Cystopurin is most effective in cutting short attacks of cystitis and relieving the frequency and pain which accompany micturition. The fact that IT EXERCISES ITS EFFECTS EQUALLY IN ALKALINE OR ACID URINE is a great help."

"I have had excellent results with Cystopurin in a case of cystitis that had proved difficult to cure with other urinary antiseptics. In this case of a woman of 50, the pain and frequency cleared up after three days of Cystopurin, and the urine was rendered sterile—a very gratifying result."



"I used Cystopurin in an obstinate case of cystitis. This improved rapidly, and I consider your preparation more useful for this purpose than other urinary antiseptics I have used."

Supplied in bulk and in tubes of 20 tablets for dispensing purposes.

TABLETS NEUTRAL ACRIFLAVINE—BOOTS

(Enteric-coated for internal administration.)

Many reports from physicians and urologists testify to the great value of oral administration of Neutral Acriflavine (Euflavine) as an adjunct to the routine local treatment of Gonorrhœa.

DOSAGE: GR. ½ TO GR. 1 T.D.S AFTER FOOD.

Preparations of Acriflavine and Neutral Acriflavine are also available in the form of Solution Tablets, Medicated Gauze, Pessaries, Bougies, and Pigment.

Further particulars and literature will gladly be sent on request.

Intestinal glands	0.05 grms.
Biliary extract	0.10 „
Lactic ferments	0.05 „
Agar-agar	0.05 „
Fiat tablet	0.35 „

Initial Daily Dose
Two Tablets

Laxatives, it is well known nowadays, must have two essential characteristics.

1. They must be biological, i.e., they must accord with and imitate in their action the natural physiological processes of the intestine.
2. They must be capable of educating the intestine, so that the habit of a laxative is not formed and the intestine can function unaided when bowel adjustment is attained.

Taxol has both these advantages.

Taxol has not the violent irritant action of many laxatives and purgatives, but stimulates the intestine by processes which resemble those of nature. The intestinal gland which is an important part of its composition acts on the intestine by reinforcing the deficient function which has culminated in constipation. This stimulating action is gentle, and does not force the weakened intestine to efforts beyond its power, which would culminate in aggravation of the constipation.

Taxol is not habit-forming. It re-educates the intestine to resumption of normal function unaided, thanks to the biological nature of its action. It contains no irritant drug of violent and artificial action to which the intestine can become accustomed. On the contrary, many stubborn cases of constipation, after a course of TAXOL, revert to normal and regular peristalsis.

APOLLO DEVELOPED DEFINITE MEDICAL ATTRIBUTES UNTIL IN HIS CAPACITY AS A DIVINE HEALER HE CAME TO BE KNOWN AS APOLLO *MEDICUS*. THE SCENE HERE REPRODUCED SUGGESTS THE SETTING OF THE RITES BY WHICH HE WAS INVOKED IN THE TIME OF THE EMPERORS. – Apollo was the first Greek god to be adopted by the Romans and retain his Greek name. The Romans first appealed to him in 433 B.C. when a pestilence afforded a respite from political troubles. A temple was vowed to Apollo on behalf of the people's health. Apollo is referred to as a definite health' deity in a Roman dedication to "Apollo Salutaris et Medicinalis." Disease was considered a mark of divine displeasure, and treatment consisted in overcoming this by religious ceremonies of purification. The illustration represents a sacrifice before an image of Apollo.

CASE OF CHRONIC MONOCYTIC LEUKAEMIA

BY

G. STEWART SMITH, M.D.

Assistant Pathologist to the Manchester City Hospitals

(WITH SPECIAL PLATE)

Although Reschad and Schilling-Torgau first described the condition in 1913, monocytic leukaemia is still a controversial subject, and it is only recently that its existence as a distinct entity has been accepted by most haematologists. It is agreed that these cases should be reported with full haematological and histological data, and the case here put on record has some features not previously described.

Clinical Notes

History.—A woman aged 48 years was admitted to Crumpsall Hospital on January 27, 1937. Three months earlier she had felt pains all over the body, especially in the neck and back, and general malaise. After resting for a month she got up, but had to return to bed as the symptoms continued. During the whole of this time she experienced frequency of micturition and thirst, and during the few weeks before admission had a feeling of heaviness in the left side of the abdomen.

Condition on Admission.—There was no pallor of the skin, but a slight cyanosis was present, and an erythematous rash appeared on the trunk. The mucous membranes were highly coloured, but nothing abnormal was found in the tongue or throat. The spleen was much enlarged, firm, and with sharply notched anterior border. The liver was slightly enlarged. The lymph glands were not palpable. No abnormality was found in the chest or the central nervous system. The urine was normal.

Progress.—Five days after admission a cough developed and catarrhal signs appeared in the chest; these persisted until death. On February 15 the general condition deteriorated and the patient became listless and semi-conscious, but there was no rise of temperature. The symptoms were thought to be due to cerebral thrombosis. Death occurred on February 17 after three weeks in hospital.

A blood count taken on February 2 showed 4,720,000 red cells per c.mm.; 70 per cent. haemoglobin; and a colour index of 0.75. The leucocytes numbered 394,000 per c.mm.: polymorphonuclears 2.5 per cent.; lymphocytes 0.5 per cent.; eosinophils 0.5 per cent.; monocytes 26 per cent.; monoblasts 11.5 per cent.; and primitive cells 59 per cent. The subsequent counts (see Table) showed little change. The Wassermann and van den Bergh reactions were negative, and the red cell fragility was within normal limits.

The monocytes, comprising 96.5 per cent. of the total count, were of three chief types, as stained by Leishman, although a rigid classification is impossible.

Table of Blood Counts

	2/2/37	12/2/37	15/2/37
Red cells per c.mm.	4,720,000	—	4,760,000
Haemoglobin per cent of normal	70.0	—	75.0
Colour index	0.75	—	0 8
Leucocytes per c.mm.	394,000	461,000	341,000
Polymorphs per cent.	2.5	4.0	3.5
Lymphocytes per cent.	0.5	0.25	0 25
Eosinophils per cent.	0 5	1 0	0 25
Basophils per cent.	—	0.25	—
Monocytes per cent.	26 0	19 0	25 0
Monoblasts per cent.	11.5	14 5	9 0
"Primitive cells" per cent.	59 0	61 0	62 0

1. *Monocytes, similar in many respects to the monocytes seen in normal blood, with an average diameter of 14 μ. The nuclei were large, lobulated, and often of unusual shape with slight reticulation. They had a moderate amount of pale blue "ground-glass" cytoplasm with occasional fine azur granules; but granules were not a prominent feature in any of these cells, and the variations in the shape of the nuclei were much greater than those seen in normal monocytes.*

2. *Monoblasts, larger than the monocytes—average diameter 18 μ—with large round or irregular pale-staining ribbed nucleus and generally two nucleoli. The cytoplasm was non-granular, and in some cells was vacuolated. Pseudopodia were seen in a few cells only.*

3. *So-called "primitive cells"—average diameter 9 μ. The nucleus, which was sometimes homogeneous, sometimes slightly ribbed, almost filled the cell, and was not uncommonly divided into two or three parts. The cytoplasm was slightly basophilic and non-granular, and typically formed a narrow rim around the nucleus.*

The oxidase reaction (Graham's method) was negative in each of these three types. Classification may often be difficult or uncertain when a large proportion of primitive cells are present, but on examination of these films it was quite clear that the three types were all of one series. Some of the points above described are shown in the photomicrographs reproduced in the Special Plate.

Post-mortem Examination

Necropsy was performed on February 18, 1937, eighteen hours after death. There was no evidence of external injury and no rash, and no enlargement of axillary, cervical, or inguinal glands. The bone marrow of the middle of the shaft of the femur was pale creamy reddish brown. The heart (227 grammes) was extremely flaccid; the endocardium showed much post-mortem staining; and the heart muscle was greyish brown. The right ventricle was dilated and the wall very thin. There was no valvular disease and no fatty streaking. The lungs contained a few easily broken down pleural adhesions on each side; both lower lobes showed congestion and oedema. The liver (1,843 grammes) was pale and friable. The spleen (*1,531 grammes, length 24 cm.*) was uniform maroon in colour and the capsule thick and wrinkled; Malpighian bodies were not evident. A few slightly enlarged lymph glands were found in the gastro-hepatic omentum. The lymph glands elsewhere in the abdomen were not enlarged. The kidneys were mottled greyish yellow, with thickened capsules, which stripped leaving a finely granular surface. The thyroid (28 grammes) contained an adenomatous nodule three-quarters of an inch in diameter in the left lobe. The brain and cerebral vessels showed no abnormality. There was extensive post-mortem staining in all the body cavities.

Histology

The Bone Marrow (fixed Zenker, stained Leishman).—Fatty areas were present. The blood vessels contained many leucocytes. Erythroblasts were very plentiful and eosinophils fairly plentiful, megalokaryocytes scanty; myelocytes were found in large numbers. The other cells were: (1) Large cells, somewhat irregular in shape, with lobulated vesicular nuclei and cytoplasm which was slightly basophilic without definite granules. These were considered to be monocytes and premonocytes. (2) Small cells with deeply staining nuclei, often in two or three divisions, and a small amount of non-granular cytoplasm. These were undoubtedly "blasts." Both these types of cells corresponded well to the cells seen in the vessels in the marrow and with those seen and described in the blood films. The oxidase stain was positive for the myelocytes and eosinophils, negative for the mononuclear cells and "blasts." The presence of much erythroblastic tissue is unusual in leukaemia, but fits in well with the fact that there was no anaemia and no abnormality of the red cells as seen in blood films. The bone marrow, in fact, showed normal myeloid and erythroblastic activity, together with collections of monocytes and their precursors. A somewhat similar bone-marrow picture has been described by Doan and Wiseman (1934).

Spleen (fixed Zenker; stained Leishman).—The capsule was thickened and there was a thin subcapsular zone of red blood cells; the Malpighian bodies were not discernible. The pulp was very compact, and consisted of red blood cells and masses of mononuclear cells which were similar to those seen in the bone marrow except that cells of Type 2, with a rather darkly staining nucleus, frequently double, were more numerous in the spleen than in the portion of marrow examined. A few of the larger cells (monoblasts) had nucleoli, and mitotic figures were frequent. The cytoplasm of the mononuclears was opaque and entirely non-granular. Nucleated red cells were scanty and polymorphonuclears absent. The arrangement of the monocytes in the spleen was not suggestive of any special origin or method of formation. There was no evidence of desquamating endothelium in the sinuses as described by Clough (1932). The absence of lymphoid tissue and polymorphonuclears is important from the point of diagnosis, and will be discussed later.

Lymph Gland (from the gastro-hepatic omentum).—The normal follicular structure was absent. Lymphocytes were present in small numbers, but the tissue was largely composed of monocytes and monoblasts as seen in the other organs. The cells lining the sinuses were well defined, but there was no evidence of proliferation or desquamation. In general the picture was that of a gland which had been infiltrated by leukaemic cells and the lymphadenoid structure was grossly disturbed.

Liver.—There was pronounced central fatty change and some increase of periportal fibrous tissue. The intercellular capillaries showed a general infiltration of monocytes with denser collections in the portal areas; the capillaries around the central vein were congested. The appearances were those of chronic venous congestion with leukaemic infiltrations of "myeloid" distribution, but not as pronounced as is usual in chronic myeloid leukaemia.

Kidney.—There was a general increase in intertubular connective tissue, with many fibroblasts. A few tubules appeared to be normal, but in most the lining showed varying degrees of degeneration up to complete necrosis and shedding of the epithelium. The glomeruli were less affected, but many showed some capsular thickening, and a few complete obliteration and fibrosis of the tuft. These changes, especially as regards the tubules and intertubular connective tissue, were diffuse and advanced, and were probably the cause of death. In both kidneys there were dense infiltrations of mononuclear cells similar to those found elsewhere. The liver, spleen, and kidney contained no free iron.

Heart Muscle.—No fatty change, but there was slight leukaemic infiltration.

Lungs.—These showed oedema and congestion, with leukaemic cells in the exudates.

Discussion

It is not proposed in this article to survey the literature of monocytic leukaemia; Dameshek (1930) and Clough (1932) reviewed all the cases published up to that time, and Gittins and Hawksley (1933) gave notes on cases reported since Dameshek's paper. To date some thirty reported cases have been published, but only six in this country (Cooke, 1931; Gittins and Hawksley, 1933; Orr, 1933, two cases; Whitby and Christie, 1935; and Israëls, 1937). Most have been acute cases, with symptoms such as stomatitis and haemorrhages, common to all acute leukaemias. In the present case death occurred from nephritis.

Accepting monocytic leukaemia as a separate disease, a chronic form, as with the other leukaemias, might be expected to occur, and the features of this case seem to warrant its recognition as an example of a chronic leukaemia of monocytic type.

The spleen, which weighed 1,531 grammes and was 24 cm. long, was much larger than has been previously described in monocytic leukaemia. Mostly in this disease the spleen is not palpably enlarged, though in a few cases there is moderate enlargement. The size of the spleen in the case here described implies chronicity. The diagnosis rests between three conditions:

1. Chronic lymphatic leukaemia.—The abnormal cells in the blood were not lymphoid as regards either nucleus or cytoplasm. There was no general enlargement of the lymphatic glands, and the lymphoid tissue in the spleen

and lymph glands was not increased, but was decreased in amount and replaced by leukaemic infiltration.

2. Chronic myeloid leukaemia.—This is the condition which presents the most difficulty in differential diagnosis, since it is admitted that the cellular infiltrations in the organs are "myeloid" in distribution and the spleen is similar in size to a chronic myeloid spleen. It has been pointed out also (Gittins and Hawksley, 1933) that monocytes or monocytoid cells may appear in large numbers in the blood during the course of myeloid leukaemia. In the present case, however, the following facts are definitely against a diagnosis of chronic myeloid leukaemia: (*a*) Polymorphonuclears did not account for more than 4 per cent. of the leucocytes in the blood, and no myelocytes or myeloblasts of usual type were seen in a total of 461,000 leucocytes per c.mm. It is difficult to picture a case of myeloid leukaemia with so high a leucocyte count without at least a fair proportion of primitive cells definitely of the granular myeloid series. (*b*) The bone marrow contained normal erythroblastic and myeloblastic elements with an intermingling of mononuclear cells. The picture was not that seen in chronic myeloid leukaemia, in which the erythroblastic elements are crowded out by all types of granulocytes and their precursors. (*c*) The oxidase reaction of the monocytic cells in the blood, bone marrow, and spleen was negative. This is strong evidence against myeloid leukaemia.

3. Chronic monocytic leukaemia.—It is obvious from the literature that many different types of cells have been observed in cases considered to be monocytic leukaemia, ranging from monocytes similar to those found in normal blood to actively phagocytic histiocytes. In this case the monoblasts and monocytes (Types 1 and 2 in the differential blood count) appear to be typical as to size of cell, shape and character of nucleus, and colour and opacity of cytoplasm. Granules, although present in very few of the maturer monocytes, definitely were a rare feature. Some typical monoblasts with mitotic figures were seen in the spleen. The negative oxidase reaction, although valuable evidence against the cells being abnormal myelocytes, does not establish their identity, since monocytes may give a varied result with this method.

The cells classed as "primitive cells," Type 3, are more difficult to place. The absence of nucleoli from most of them, together with the fact that the nucleus was often divided into two or three parts, is quite unlike the picture of either myeloblasts or lymphoblasts; except for the absence of granules they are very similar to cells drawn and described by Doan and Wiseman (1934) as premonocytes in a case of monocytic leukaemia with a long history, ending in death from intercurrent disease. They state that "multinucleated cells are encountered frequently both in the blood and in the tissues in monocytic leukaemia." The name "premonocyte" suggests that they considered them to occupy a position between the monoblast and the mature monocyte. The lack of differentiation, combined with other features, however, leads me to a tentative conclusion that they are more primitive still than the large monoblasts, although of the same series. The supravital staining methods were not used in this case, but it is doubtful, in view of the contradictory findings of different workers (summarized by Hall, 1930), whether they add anything of diagnostic importance to the information obtained from dry smears.

Two features are worthy of special comment. (*a*) The fact that active erythropoiesis was going on in the bone marrow, and the corresponding absence of any anaemia in spite of a leucocytosis of 500,000 per c.mm. A progressive anaemia is almost the rule in leukaemia of this degree. (*b*) The spleen was densely infiltrated with monocytes and primitive cells, the latter being more plentiful than in the bone marrow, suggesting that the monocytes were being produced chiefly in the spleen.

Summary

1. A case of monocytic leukaemia is described, with haematological and histological findings.

2. The disease is rare, and a case with the high leucocyte count here recorded and the greatly enlarged spleen has not previously been reported.

3. It is considered that the case is one of chronic monocytic leukaemia.

I wish to thank Dr. C. S. D. Don, senior visiting physician to Crumpsall Hospital, for permission to publish this case, and Dr. G. D. Dawson and Dr. M. C. G. Israëls for helpful criticism.

VESICAL EXTROVERSION WITH CONTROL OF MICTURITION

BY

A. RALPH THOMPSON, Ch.M., F.R.C.S.

Consulting Surgeon, Genito-Urinary Department, Guy's Hospital

(WITH SPECIAL PLATE)

The two cases of extroversion of the bladder recorded in this paper are worthy of attention in that they show the value of as complete a clinical examination in this type of case as is possible. For this purpose an anaesthetic should be given, and this has the additional advantage of allowing an artist to draw what is seen, at his leisure, and under the guidance of the surgeon. The cases also show that an operation directed towards closure of the bladder may, under the conditions which are to be noted, be of great value in leading to voluntary control of micturition, with as little disturbance of the parts as is possible. The main importance of the cases is that there was a normal proximal urethra developed in association with an extroversion of the bladder. This possibility is not generally recognized, but it is so important that no excuse need be offered for its early mention. For a very long time I have suspected that even in cases of advanced extroversion of the bladder much more of the normal urethra may be developed than authorities have apparently believed. In support of this assertion three cases of mine may be mentioned that seem to prove the occurrence of such a condition. In the absence of the two main cases which form the subject of this paper, the possibility of there being a normal proximal urethra is difficult of demonstration or conception. One of these cases, however, undoubtedly shows the presence of a normal proximal urethra. Two illustrations are here shown (Special Plate, Figs. I and 2) the originals of which are

water-colour pictures executed by Miss M. Barford, sister at Guy's Hospital, and Miss Miall-Smith, formerly house-surgeon at the Victoria Hospital for Children.

Case I

The first case is the more important. A child aged 2 years was sent to me by Dr. G. B. Muriel of Whitehaven, Cumberland. The patient was quite healthy, and mentally most intelligent. I had no hesitation in pronouncing the child to be a boy. An anaesthetic was given and as complete an examination made as was possible. Miss Barford also took the opportunity to make a water-colour drawing of the condition (Fig. 1). This examination was done in July, 1936. At the end of the month the boy developed whooping-cough, and was sent to stay with an aunt who took very great care of him. The opinion as to the sex of the child was confirmed in September by the formation of a painful non-inflammatory swelling in the left groin, and the descent of the left testicle occurred. Later on, when all pain and abdominal swelling had gone, Mr. Bromley confirmed my opinion that the swelling was the left testicle. In October, 1936, an operation was performed by me at the Putney Hospital. The bladder was constructed; complete union of the parts occurred, and the patient gained control of micturition. This control of micturition has persisted, and early in June of this year an aunt who had taken charge of the infant wrote me as follows: "He can hold his water . . . all he complains of is pain in that lump [the descending testicle], otherwise he is fine and never wets his clothes." This good result is in great part due to Mr. Bromley, who very kindly helped me at the operation, and to the medical and nursing staff at Putney, who all showed great interest.

The details of the case are as follows. The mother gave the information that the cord was cut at birth as usual. After admission an examination was carried out under an anaesthetic. Mr. W. M. Dunham, then dresser in the genito-urinary department at Guy's Hospital, helped me, and it is largely due to him that the exact condition of affairs was discovered. There was a distinct extroversion of the wall of the bladder, which was smaller than usual in my experience of these cases (about thirty in number). This was situated in the lower part of the anterior abdominal wall. The extroversion of the bladder was circular and umbilicated, and measured three-quarters of an inch in diameter. The surface was distinctly red, and was clearly that of a mucous membrane. In the perineum there was a similarly coloured groove or gutter, which passed downwards and backwards towards the anus, but did not reach as far. The extroverted bladder was separated from the perineal gutter or groove by a bridge of skin which was not more than a third of an inch wide. The gutter was about an inch long and half an inch wide. It stopped short of the anus by one inch.

Before a further description of the parts is offered it may be pointed out that three common conditions present with ectopia vesicae were evident in this case. There were wide divarication of the two rectus muscles of the abdomen in the lower half, wide divarication of the pubic bones, and a general raising up of the bladder, perineum, and anus towards the head of the patient. I had often before noted this last point, and the first two observations are well known and constant in cases of extroversion of the bladder and so-called epispadias. There was a large ventral hernia, and at the upper part of this and situated slightly to the right of the midline appeared the remains of the umbilical cord, quite normal in appearance save that the navel was slightly stretched by the hernial protrusion.

The important fact of this case was found in the perineal gutter. There was a small protuberance on each side of the perineal gutter which extended downwards and inwards towards the midline. Each protuberance was not unlike a penis on a very diminutive scale, and I did not doubt that it was an incomplete phallic eminence which had remained bifid. In the perineal gutter were five orifices; the first and most important was median and single, and lay in front of the others. On Mr. Dunham's suggestion I passed a probe through this orifice, and another through the bladder opening, and the probes touched each other, making a metallic click.

After twenty years of some experience of these cases a normal proximal urethra was recognized by me as associated with an extroversion of the bladder. Behind this opening were two paired holes, one of each pair by the side of the midline and close to it. The two posterior orifices were oval, an eighth of an inch long and a sixteenth of an inch broad. The two anterior orifices were of similar size and shape. It was found that the two posterior orifices were only divided by a bridle-like structure, and opened into a single cavity. This cavity passed upwards for about an inch. The two orifices in front of them opened into distinct cavities which passed upwards and backwards. None of these holes appeared to make any connexion with the bladder, and though they are probably of very great interest, further discussion as to their nature would be out of place here. It is with the anterior orifice that we are concerned. For although it was incomplete it was a true urethra, and for this reason the capability of controlling the act of micturition might exist. Up to now I think the possibility of such a condition being present has hardly received the attention it deserves. It was not an easy procedure to introduce a probe through the orifice into the bladder, but I am quite sure that no structure was perforated and that the difficulty was caused in fact by a slight curve in the passage and perhaps by folds of mucous membrane. It is solely because of the presence of this passage that I have been tempted to place the case on record. But this case is not, I am disposed to think, the only one it has fallen to my lot to see and observe partially. But before describing the second case I may say that in one case of extroversion of the bladder and in two cases of so-called epispadias there has been some evidence, as proved by dissection or by the pointing of a stone in the perineum of a case of extroversion, that more of the proximal urethra may have been developed than was obvious at a superficial examination.

Case II

This child was born in the Guy's district at the end of 1917. The birth was normal and the cord was cut in the usual manner. The diagnosis, in which I shared, was that the baby was a female. She was christened Frances, and in this connexion it may be noted that the names of Cecil and Evelyn are also useful for these babies of doubtful sex rather than the unequivocal Peter or Margaret.

As soon as the baby was weaned it was transferred to the Victoria Hospital for Children. Miss Miall-Smith not only took trouble about making a water-colour sketch of the anatomy but was also most assiduous in looking after the case before, during, and after the operation. The first operation, undertaken in the first three months of life, was a complete failure, but a second was a complete success, and this was carried out in the next three months, when the parts had resumed their former

condition. A small orifice was left in the wound deliberately, for the purpose of allowing urine to drain away from the bladder. At the end of 1918, when the baby was about a year old, he was admitted to a London infirmary suffering from bronchopneumonia. I wrote personally to the superintendent telling him of the importance of the case, and he was kind enough to reply, stating that an occasional drop of urine was discoverable at the orifice of a small fistula in the wound. The baby died from the pneumonia; but I was not informed of this, so was not present at any further examination. I saw the mother afterwards and she informed me that she thought the young infant had gained some control over the flow of urine; this remark supports what was said by the medical superintendent at the infirmary. It may therefore be claimed that there had been control gained to some extent though the baby was only 14 months old when death occurred. In view of Case I, recorded above, I cannot help but think that the control in this second case came through a normal proximal urethra being present, and that the fistula left at the second operation may have been closing up at the time of death. The anatomical condition as studied clinically was as follows. The infant was well developed and not at all fretful, and soon took well to hospital life. The condition found is well shown in the illustration (Fig. 2, Special Plate). There was a large extroversion of the bladder, measuring two inches laterally and one and a half inches from above downwards. Both ureteric orifices were visible on the surface of the protruded bladder. Below the level of the bladder was a bridge of skin which passed across the middle line and connected the two sides of the abdomen. Below this bridge of skin there was what may be called a perineum. At the front part of this was a circular hole, which was situated upon the summit of a distinct though small protuberance.

At about the level of this protuberance and orifice and on each side of the midline was a symmetrical body exactly similar to a small penis. This projected inwards and downwards, and was about half an inch in length. The tips of these paired bodies were separated by a distance of half an inch. Behind and below these prominences there was a bilateral swelling, conical in shape and also directed inwards and downwards. These eminences were yellow in colour; they did not project so far inwards as the previous ones, and were three-quarters of an inch from each other. Behind them, but in the middle line, was the anus, which was normal. Some years after seeing and operating upon this case I came to the tardy but inevitable conclusion that the child was a male. The anterior projections were parts of a bifid penis, and the eminences behind these were undeveloped but distinct parts of the scrotum.

Now in view of the previous case I am drawn to the conclusion that the orifice mentioned as lying in the midline was really a partially developed urethra. I cannot help but think that after the second operation the baby passed water through this orifice, for we know from the infirmary report that only an occasional drop of urine was found at the site of the small fistula that had been left at the operation.

S. G. Shattock laid it down, when at the Royal College of Surgeons, that hypospadias could not occur with an extroversion of the bladder. I have a series of photographs of a male foetus which was born dead. It had a large extroversion of the bladder on the surface of which the bowel opened. In this case, however, there was a definite penis with a fully formed scrotum, and also a prepuce, and on the under surface of the glans penis was an opening which led backwards along the normal course of the urethra. In fact, it appeared to be a normal urethra. This passage did not, however, make a connexion with the bladder, but passed directly into the vesiculae seminales, as shown by Dr. G. W. Nicholson. The case is most interesting, but need not detain us now; we must be careful, however, in accepting as true a statement made even by such an authority as the late Professor Shattock.

It is sufficient here to state that in two cases of extroversion of the bladder proximal urethras were present which were capable of controlling micturition.

For the true nature of this incompletely developed urethra I must refer to other articles I have written on this subject.

The Operation on Case I

Thanks to the assistance of Mr. Bromley and my former house-surgeon, Mr. John Rowlands, the operation was quite quickly performed. After an anaesthetic had been given and continued the extroverted bladder was pushed back into the abdomen, and an incision was carried round the mucosa, of which a good edge was exposed. Catgut sutures were used to join the edges transversely. The circular incision around the mucous membrane was extended on each side transversely, for about three-quarters of an inch. The skin edges were everted widely, and a broadish linear area of subcutaneous tissue was thus exposed. Lembert catgut sutures were applied to this surface on each side of the long axis of the wound, drawn together and tied, and then cut short. Thus the bladder was buried deeply with a good covering of subcutaneous tissue. The skin edges were then united with fine salmon-gut sutures. A collodion dressing was applied and the patient was sent back to bed. Instructions were given that when he had recovered from the anaesthetic he was to be allowed to do as he wanted, and was to be permitted to walk about the ward if he wished. I very greatly object to having these babies tied down in bed. These conditions are not natural ones, and the crying induced by the confinement does a great deal of harm. As there was no catheter in the bladder natural conditions were called for. The patient at once was able to hold his water, according to Mr. Rowlands; and continued to do so except when he wished to micturate, at which time he passed urine in a good stream. This happy result continues, and naturally the parents are delighted. The salmon-gut sutures were removed about the tenth day. The normal proximal urethra is performing its duty of controlling micturition.

Very much the same operation was performed on Case II (the first in point of time). As I have said already, the first operation was a failure, the second was a success.

Commentary

The important point which I have tried to bring out in this paper is that whilst there was in both cases a well-marked extroversion of the bladder, there was in one certainly, and in the other probably, a proximal urethra capable of controlling the flow of urine. In such cases construction of the bladder as a hollow cavity may be the operation of choice rather than the more severe and much more difficult operations of uniting the urinary and alimentary tracts, with which the names of Stiles, Nitch, and Grey Turner are so honourably associated in Great Britain. I should like to add a personal point. It is curious that at the end of eighteen years a second case should explain the anatomy and surgery of a prior one.

TUBO-UTERINE IMPLANTATION FOR STERILITY

FOLLOWED BY FULL-TERM PREGNANCY

BY

V. B. GREEN-ARMYTAGE, M.D., F.R.C.P., F.C.O.G.

Gynaecologist to the West London Hospital, Hammersmith; Visiting Gynaecologist and Obstetrician on the Staff of the British Postgraduate College, Hammersmith

(WITH SPECIAL PLATE)

The first tubal implantation resulting in full-term pregnancy was reported by Shaw and Cullen in 1921. The second recorded was by Unterberger in 1925. Von Graff in 1936 published the results of the seventy tubo-uterine implantations reported in the literature. Of these twenty-six were followed by pregnancy; only twenty-three, however, went to full term, one ended prematurely, one terminated in abortion, and one was an ectopic gestation—that is, an incidence of pregnancy amounting to 32.9 per cent.

Greenhill (1937), in order to determine the sentiment of American gynaecologists concerning salpingostomy and tubal implantation for sterility, sent a questionary to members of the American Gynecological and Obstetrical Society and the American Association of Obstetricians, Gynaecologists, and Abdominal Surgeons. One hundred and seven replies were received.

Fifty-three of the specialists had never performed a salpingostomy. Eighty-eight had never considered tubal implantation as an operation worth performing for the purpose of overcoming sterility.

On the other hand, thirty-five were strongly in favour of plastic operations upon the tubes, believing that the misery associated with sterility justifies the technique, however meticulous, however disappointing. Their results worked out at one pregnancy for every fifteen operations, and one full-term living child for every twenty-two abdominal sections.

The same atmosphere of pessimism is found in this country. For instance, Beckwith Whitehouse in the fourth edition (1935) of Eden and Lockyer writes: "The technique requires considerable skill and the operation is not lightly to be undertaken. The method is as yet too recent and the published records of success too few to express a considered opinion as to its ultimate value." Later, however, he states that he has had one successful case.

Similarly at the sixth British Congress of Obstetricians and Gynaecologists, 1936, after a stimulating paper on the subject by Bethel Solomons (1936), the majority of those present expressed the opinion that the abdomen should not as a rule be opened directly for the purpose of operating on the Fallopian tubes. On the other hand, a minority following the dictum of Harvey "to seek out and study the secrets of Nature by way of experiment" thought that all cases of tubal sterility should be carefully investigated with reference to previous history, menstruation, etc., and emphasized the necessity of methods of precision being first used to determine the site of obstruction, by far the most scientific being that of hysterosalpingography. They were of the opinion that if the case were suitable a plastic operation was worth while, no matter what part of the tube was involved.

Solomons stated that he had sent a questionary to 150 world-known gynaecologists. Fifty-three replies were received from those who operated upon the tubes. The answers showed that the incidence of pregnancy, after salpingostomy alone, averaged from 8 to 10 per cent., though the figures of Rubin, Norris, Blair-Bell, and Gellhorn were very considerably better. After tubal implantation only six full-term live children were reported. In two cases abortion occurred.

It is significant that only thirteen out of the fifty-three surgeons who answered the questionary stated that they tested the patency of the tubes after operation. This is the acid test of any technique employed, and if not applied in every case as a routine measure, it were perhaps better not to operate at all. For my own part I believe the best test from both the physical and the psychological point of view is the salpingogram, which cannot lie and which should be taken two weeks, ten weeks, and twenty weeks after whatever operation has been performed. Using the Seguy apparatus (Drapier et Cie), put on the English market by Allen and Hanburys, radiographs can be taken without pain or anaesthetic, although if need be they can be done under morphine or evipan.

It is possible that a careful choice of cases and improved technique will yield in the future a larger incidence of success to those who are willing to operate; for, provided there is no complete occlusion of the Fallopian tubes by gonorrhoeal, post-abortal, puerperal, or tuberculous infection and the semen of the husband is normal, there is no contraindication. Moreover, it must be realized that when the history and clinical findings are assured we have in salpingography a method which enables us to determine the site of occlusion and thereby base the strategy and tactics of any proposed procedure.

Operative Methods

Hitherto many surgeons have followed the technique of Douay (1936), Seguy, and Blair-Bell (1934)—that is, after applying a myomectomy clamp the cornu of the uterus comprising the interstitial portion of the tube is resected. The end of each tube having been bifurcated, it is then threaded with silkworm-gut and drawn within the uterine cavity and sewn *in situ* with fine catgut as in Fig. A.

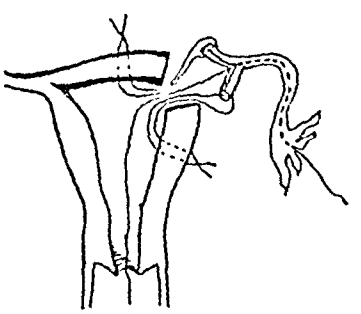

FIG. A.—After wedge resection of the cornu and resection of the occluded isthmial part of the tube, it is bifurcated, threaded with gut, and drawn into the lumen of the uterus. It is then lightly sutured *in situ*.

Great care is taken, when the cut cornual surfaces are joined, that there is no strangulation of the implanted tube. A week later the silkworm-gut is removed. The tubes are tested with air or lipiodol from time to time.

Others have adopted the method of Solomons—that is, the uterus is first bisected. After excising the occluded area the distal and patent part of the tube is threaded with catgut. The cornu of the uterus is shaved to expose the line of the interstitial part of the tube, which is then expanded sufficiently with dilators to draw the threaded tubes into the lumen of the uterine cavity; fine anchoring sutures are then applied through the bisected uterus to keep the implanted tubes in place.

The technique of Bonney (1936) is the simplest. After applying his myomectomy clamp and ring forceps to the infundibulo-pelvic ligaments, he splits transversely the fundus of the uterus from cornu to cornu until the cavity of the uterus is opened. The occluded isthmial part of the tubes having been excised, a strand of silkworm-gut is threaded along each tube from the outer to the inner end. The tube ends are now laid carefully in the line of the transverse fundal incision so that the free amputated ends of the tubes are projecting actually into the cavity of the uterus. The long ends of the silkworm-gut are passed through the eye of a special dilator and drawn into the vagina after releasing the clamp. The tubes are fixed *in situ* by interrupted sutures of fine catgut, and as an additional safeguard a few sutures are inserted through the muscle of the tubes to the outer part of the cornual incision on each side. The silkworm-gut is removed about the tenth day. Mr. Bonney (1937) has had 18 per cent. of successes from salpingostomy, and has recorded five pregnancies following double and single implantation of the tubes with or without simultaneous salpingostomy. His results are inspiring and dispel pessimism.

It is proposed to describe a modification of this technique which has recently resulted in a full-term pregnancy.

Illustrative Case

Mrs. D., aged 25, married two years, was admitted with a history of four miscarriages to the West London Hospital on March 4, 1933, for retention of urine and intractable vomiting. The uterus was twelve weeks pregnant, retroverted, incarcerated, and fixed. Endeavour was made under an anaesthetic to replace it on two consecutive days, with failure on both occasions. The abdomen was therefore opened. It was seen that the fundus was fixed by dense adhesions to the posterior parietes, presumably subsequent to one or other of the four previous miscarriages. A modified Gilliam operation was performed. She went to full term, and as she had a typical funnel-shaped pelvis, demonstrated by measurements and radiographs, a lower-segment Caesarean section was performed on November 22, 1933.

Seeing that she had had four miscarriages and already two abdominal operations (one previous to admission for appendicitis), she and her husband demanded that she should be sterilized. Against strong advice this was insisted upon. Sterilization by excision of the cornual portions of the tubes was performed. Three days later the infant died, and was found at necropsy to have congenital heart disease (patent foramen ovale) and atelectasis.

In August, 1935, being very miserable, she came to the out-patient department asking if she could have another baby. Rather diffidently I informed her of such a possibility if she would submit to the operation of tubo-uterine implantation. Fig. 1 (see Plate) shows the uterus before operation. On October 20, 1935, with the following modifications, the Bonney technique was used. (Fig. 2 shows the result six months after operation.)

The Modified Bonney Technique

First a twelve-inch-long probe is passed eye forwards from the vagina through the cervix up to the top of the fundus uteri. It is then clamped *in situ* by a vulsellum on the cervix. On opening the abdomen a myomectomy clamp is placed round the cervix, and ring forceps are applied on the infundibulo-pelvic ligaments.

The proximal stenosed ends having been excised, a fine bodkin threaded with a long piece of Japanese silkworm-gut is passed gently through each tube so that about two inches remain visible at the distal end of the tubes, and about fourteen inches are available at the proximal ends to be threaded into the eye of the probe that is now exposed by making a transverse incision across the fundus of the uterus from cornu to cornu.

Each threaded tube with its intact mesentery is now snugly and rapidly placed in the V-shaped groove at each cornu so that about a quarter of an inch of each proximal end projects well into the endometrial cavity. Having lightly anchored the muscle wall of the tube with fine catgut at each cornu, the free long ends of silkworm-gut are threaded into the eye of the probe which has been referred to. The clamp being relaxed, the vulsellum on the cervix is released by an assistant and the probe slowly withdrawn, carrying with it the two lengths of gut. These are sutured to each side of the vaginal outlet at the end of the operation. The clamp and ring forceps being removed, the fundal incision is then closed with deep and superficial catgut as in a Caesarean section, particular attention being taken of the cornual portions, lest any undue compression of the buried though threaded tubes occurs. The technique with perfect haemostasis is not difficult, and can be completed under the hour.

The silkworm-gut is withdrawn in the ward on the twelfth day. The advantage of Japanese silkworm-gut is that it softens and it does not disintegrate or irritate.

On September 8, 1936, Mrs. D. reported that she had missed two periods. Examination showed that she was pregnant. She was carefully watched during the antenatal period. Six weeks before she was due she was admitted for observation and rest, lest labour should come on prematurely or the fundal scar give. *X*-ray photographs showed at first a breech; after two weeks spontaneous version occurred. On April 7, 1937, a classical Caesarean section was performed. A healthy child weighing 5 lb. 10 oz. was delivered. There were a good many adhesions of omentum to the top of the uterus where the fundal incision had been made. These were not interfered with. The implanted tubes measured only two inches in length. No sterilization was done. The postnatal period was afebrile and uneventful. She left hospital on the twenty-eighth day, the baby weighing 6 lb.

Commentary

The case is reported in order to stimulate others to undertake plastic operations upon the tubes. Hitherto my personal success with salpingostomies has been four living children, the fruit of twenty-five laparotomies. Tubo-uterine implantation has been done thrice with one success.

The modified technique described is not difficult. The complete haemostasis obtained with clamp and ring forceps makes technical tactics easy.

Hitherto many gynaecologists have considered that operation is hardly worth while unless the Fallopian tubes are only occluded at the fimbrial ends; but when one considers how very miserable the sterile woman often is it does seem proper in a suitable case to give her the option of surgery provided some portion of the tube or tubes is patent, for, in the words of Bethel Solomons, "just as an occasional good golf shot impels the worst player to persist with the game, so occasional success in plastic surgery of the Fallopian tubes will impel the gynaecologist to continue his efforts and improve his technique, thereby achieving better results."

GAUCHER'S DISEASE OF THE LUNGS

BY

BERNARD MYERS, C.M.G., M.D., F.R.C.P.

(WITH SPECIAL PLATE)

Gaucher's disease is comparatively rare, and affection of the lungs by it still more rare. So far I have not been able to find records of a case in this country similar to the one I am describing. Gaucher's disease has been described as a non-hereditary, congenital, familial disease due to changed lipoid metabolism, which produces an abnormal substance called kerasin. More cases occur in females than in males. It is believed that certain cells of the reticulo-endothelial system store the kerasin to form what are called typical Gaucher cells. These cells are chiefly found in the spleen, liver, lymph glands, and bone marrow.

This affection is recognized clinically by the distinct enlargement of the spleen and liver, the pinguecula-like thickenings of the conjunctivae, a light yellowish-brown pigmentation of the skin and sclera, various changes in the bones, leucopenia, thrombocytopenia, and the haemorrhagic diathesis. Sometimes the lymph glands are enlarged. Ascites is only occasionally seen. The pain experienced over the bones particularly is that of a dull ache, but the pain over the spleen and liver, and I believe also in the lungs, is apt to be sharper. The disease may be encountered at any time from birth to about middle age.

Diagnosis is made from the symptoms described above, but especially from the peculiar tint of the skin, splenomegaly, and usually hepatomegaly without ascites, flask-like expansion of the lower ends of the femora accompanied by dull ache or even sharp pain, a raised temperature, leucopenia, and hypochromic anaemia, and is clinched, if necessary, by a splenic puncture and the finding of Gaucher cells, or by finding these cells after biopsy of a gland.

Sobotka and others (1933) state: "At least three pathological entities of generalized 'lipoid storage' disease or lipoidosis have been distinguished from clinical and pathological evidence and confirmed by chemical investigations: (1) Gaucher's splenomegaly, characterized by large deposits of a cerebroside; kerasin, in spleen and liver; (2) Niemann-Pick's disease, in which the phosphatide and cholesterol contents of the viscera, the bone marrow, and the brain are increased at the expense of neutral fat; (3) Schüller-Christian's disease, with replacement of the bone tissue by cholesterol deposits."

Case History

A little girl aged 2 years and 7 months was admitted to the Royal Waterloo Hospital on September 16, 1931, on account of a distinctly enlarged abdomen, and general weakness and illness. Upon examination it was found that she was small for her age and appeared to be very ill indeed. There was a slight icteric tint of the skin generally, which also affected the conjunctivae to some extent. The abdominal prominence was due to a greatly enlarged spleen, which reached to the pubes and just to the right of the middle line. Its texture was moderately firm and smooth. The liver was enlarged two fingerbreadths. There had been three attacks of epistaxis during the past few months, the last, a month previously, having been quite severe. The coagulation time of the blood was normal; the bleeding-time a little prolonged—6 minutes. The red blood corpuscles were 800,000 per c.mm. on admission and the haemoglobin 19 per cent., but this was reduced to 16 per cent. two days later. The white blood corpuscles numbered 3,100. The Wassermann reaction was negative, and the fragility test normal. The van den Bergh test, both direct and indirect, was negative. The urine was normal. Examination of the stools showed a very slight excess of split fat (fatty acid), but no unsplit fat. No undigested muscle or starch was seen.

The child evidently had had an enlarged abdomen since the early months of life and attended many clinics, etc., and had been apparently regarded as a rare case of rickets. However, no sign of the latter was evident when the child was admitted to hospital. The general appearance, the spleen, the leucopenia, the epistaxis, and anaemia seemed to fit in with the diagnosis of Gaucher's disease, which was made tentatively. It was intended to do a splenic puncture and settle the diagnosis by a microscopical examination of the cells, but on account of the child's desperate condition it was decided not to; consequently, two days after admission, as a possible chance of saving her life, I asked my colleague, Mr. Rodney Maingot, to perform splenectomy. This was done on September 19, 1931. The spleen weighed 39 oz., and both Dr. Knott and Professor Kettle found typical Gaucher cells present. No similar case had occurred in the family.

Contrary to expectation the little patient made a perfect recovery, and within three to four months the blood count was practically normal.

During April, 1932, she was readmitted to hospital with great pain at the lower end of the right femur. The condition was diagnosed as osteomyelitis, and Mr. St. John Buxton operated and found greyish-green pus from which a few colonies of *Staphylococcus albus* were grown. Gaucher cells were present in the bony canals of necrosed bone taken away at the operation. Looking back on this case, I am not sure if it was not the ordinary invasion by Gaucher cells which occurs in some of the bones in Gaucher's disease and not osteomyelitis.

During the next two years the patient complained of pain in the back, which was found by *x*-ray examination to be accompanied by gradual atrophy of the bodies of some six or seven dorsal vertebrae, and was obviously due to the Gaucher process. Mr. St. John Buxton undertook to treat the condition.

The following year there was a certain amount of enlargement of the glands in the neck and groin; and pain with a moderately high temperature appeared suddenly, accompanying enlargement of the lower end of the left femur. *X*-ray examination showed the condition to be typical of Gaucher's disease. No operation was done; the temperature and pain gradually disappeared, but the flask-like expanded appearance of the lower end of the left femur remained (as had happened to the right femur).

In August, 1935, the child was again admitted into hospital with what at first sight seemed to be whooping-cough; but on going into the history thoroughly, and taking into consideration the peculiar nature of the cough, the condition appeared to be produced by pressure on the bronchi. Great pain was present behind the sternum, especially the lower end, for which small doses of morphine alone gave relief. The temperature was moderately high, and the respirations and pulse increased in frequency. Careful examination revealed some dullness below the left clavicle and gave the signs of what appeared to be lobar pneumonia. The severe substernal pain gradually disappeared after about a fortnight. Fresh areas of dullness were noted in various parts of the lungs, and the sputum was fairly copious. During this time and the next year the sputum was examined about twenty times for Gaucher cells, but the result was always negative. A number of *x*-ray examinations, made at first fortnightly and afterwards monthly, showed a gradually increasing process spreading from the mediastinum towards each axillary region, the dullness becoming more and more marked. The area of bronchial breathing below the left clavicle persisted, and similar areas gradually became manifest over various parts of the front and back of the lungs. Many medium moist rales were heard, and these persisted. Last November a sudden great pain was felt by the child in the

right axillary region, and very definite signs of pleurisy were found there.

The blood count in August, 1935, when the child was 6½ years old, was: red cells, 5,200,000; haemoglobin, 87 per cent.; colour index, 0.82; white cells, 73,600; polymorphonuclears, 65 per cent.; lymphocytes, 27 per cent. In making the differential count the pathologist stated that many dead or basket cells were found. The platelets were fairly numerous.

The pulmonary process was certainly different from anything I had seen in a child before, and as Gaucher's disease was present in other parts of the reticulo-endothelial system the pulmonary condition was looked upon as being probably due to the same affection.

During 1935 and 1936 the liver became greatly enlarged and reached nearly to the pubes, also extending beyond the umbilicus into the left hypochondriac region. The child's growth was certainly being interfered with by the faulty fatty metabolism present. She was distinctly smaller and much lighter in weight than her sister, who was two years younger. During 1936 various nervous manifestations became evident; she would become irritable without cause, and developed movements of the eyes, mouth, nose, face, and neck, often for only a few days at a time, but they never entirely disappeared.

Death took place on January 15, 1937, and as a partial necropsy was allowed the diagnosis of Gaucher's disease was verified. I append reports.

Pathological Report

The following are the necropsy findings reported by Dr. F. A. Knott:

The body showed considerable wasting and, for the child's age, underdevelopment of the muscles and bony skeleton. The dorsal vertebrae were markedly arched forward owing to the collapse of some of their bodies. The abdomen was very protuberant because of the greatly enlarged liver. There were no bruises or pigmentation, and no oedema.

On opening the abdomen the most striking feature was an enormously enlarged liver, which weighed 3 lb. 7 oz. Its surface was smooth, and the enlargement occurred equally throughout all the lobes. The gall-bladder and biliary tracts were normal. The liver had a pale pink colour as a whole, with irregular patches of dull yellow. It had formed no adhesions.

The intestines showed no abnormality, and the kidneys and genito-urinary tract appeared normal, but there was considerable enlargement of practically all the abdominal glands, this being more marked in the upper than in the lower abdomen.

When the thorax was opened the heart and great vessels were found to be normal, except that they were variously displaced through enlargement of the mediastinal glands, the enlargement continuing into the root of each lung. The pulmonary appearances are described below. There were no pleural effusions or adhesions. The thymus, thyroid, larynx, and pharynx were normal; the brain was not examined.

The spleen had already been removed about five and a half years previously, and at that time weighed 2 lb. 7 oz. Its general and histological appearances had been reported as typical of a Gaucher spleen.

Specimens for section were taken from the liver, from glands in various parts of the body where noticeable enlargement had occurred, from a rib, a part of the sternum, the root of a lung, a small solidified area in the lung, the kidney, the pancreas, and heart muscle.

Large masses of Gaucher cells were found in every instance of glandular enlargement, and in all the samples of bone marrow examined; the kidney, pancreas, and heart muscle were free. In the liver enormous collections of these cells appeared, pushing aside the normal liver tissue, which on the whole had undergone little degeneration. In sharp contrast, owing to its location inside the bones, the bone marrow was very largely compressed and displaced, and the total functioning marrow must have been much below normal. The changes in the bodies of the vertebrae were due to Gaucher deposition and pressure damage.

In short, the characteristic appearances were that at all possible sites reticulo-endothelial deposition of Gaucher substance had taken place with compression and displacement of neighbouring cells, but without producing further damage than would arise from compression.

The immediate cause of death was to be found in a simple terminal, mainly basal, bronchopneumonia; but the findings in the lungs had an interest beyond this, because they had clearly been involved in the primary Gaucher disease before the final infection took place.

COMMENTARY ON THE FINDINGS

This case illustrates particularly well the reasons for classifying Gaucher's disease among the reticulo-endothelioses. Not only were the liver, spleen, larger lymph glands, and the bone marrow packed with large masses of typical cells containing the non-doubly refractive Gaucher substance, but collections of these cells could be seen wherever lymph nodes occurred.

This process was found to account for the early physical signs noted in the patient's chest long before there was any indication of bronchopneumonia. At the post-mortem examination the mediastinal and hilum glands were all grossly enlarged and contained masses of Gaucher cells, with the result that the roots of both lungs were apparently extensively "invaded" by the disease, as seen by the increased root shadows in the radiographs and by the physical signs.

But another feature was noticeable, particularly in the upper lobes. In many of the small subserous and interlobular lymph nodes the reticulo-endothelial cells were loaded with Gaucher substance, producing a series of small apparently solidified areas, the neighbouring air spaces being markedly compressed. In between the compressed areas the lung tissue was relatively normal, the only change being the very recent terminal, mainly basal, bronchopneumonia. There was no evidence of old or recent tubercle, and the changes first noted clinically in the lungs were undoubtedly due to deposition of the Gaucher material, even in such outlying portions of the reticulo-endothelial system as the distal lymphatic system of the lungs.

Review of the Literature

Although, as I have stated, I have not succeeded in finding records of a case of Gaucher's disease affecting the lungs in England, one has been published in France by Merklen, Waitz, and Warter (1933) on the "maladie de Gaucher," in which typical Gaucher cells were found in the sputum. They state: "L'expectoration permanente pendant plusieurs mois de crachets muqueux, l'abondance de cellules constituant parfois des amas considérables, la proportion notable et constante de cellules de Gaucher typiques nous permettant de décrire une forme pulmonaire

de la maladie de Gaucher." The above was a typical case of Gaucher's disease affecting the spleen, liver, femora, and the vertebral column. Epistaxis occurred; the patient was 51 years of age; and anaemia was present along with leucopenia.

Although we repeatedly examined the sputum of our own patient, we never discovered Gaucher cells in it; still, the case quoted above shows that such can occur, and they therefore should be looked for.

I would like to refer here to "Studies on the Chemistry of Gaucher's Disease: An Analysis of Three Spleens," by R. H. S. Thompson and G. Payling Wright (1937). They state "that the essential pathological change is a specific storage of kerasin. Concerning the origin of this kerasin or its mode of accumulation in the reticulo-endothelial cells throughout the body nothing at present is known, but two hypotheses may be suggested for the aetiology of the condition. In the first place the distended 'Gaucher cells' may be merely the result of an absorptive action of the histiocytes on an increased blood kerasin." They continue: "An alternative theory, based on the assumption that the galactolipins are possible important intermediaries in the antibody responses of the reticulo-endothelial system, suggests itself as the result of recent work on certain aspects of immunological chemistry." They state, further: "In view of this work, therefore, it is conceivable that the galactolipins, whose physiological role in the body is at present unknown, may play a part in the production of antibodies by the reticulo-endothelial cells, and that Gaucher's disease may be some 'inborn error of metabolism' of the mechanism responsible for some stage in the antibody production of the body, whereby excessive quantities of kerasin are synthesized and stored by the reticulo-endothelial cells."

Summary

A case of typical Gaucher's disease in a little girl is described in which the spleen, liver, both femora, some of the dorsal vertebrae, lymph glands, and the lungs were affected.

The affection of the lungs by this disease must be extremely rare, for the only other definite case so far noted is quoted in the French literature.

The most recent views on the pathological chemistry of Gaucher's disease are stated.

In the Special Plate photomicrographs are reproduced of sections of the liver (Fig. 1), a lymphatic gland (Fig. 2), the bone marrow of a rib (Fig. 3), the spleen (Fig. 4), and the lung (Fig. 5). Fig 6 is a reproduction of a radiograph taken four months before death and showing clearly the extension of the Gaucher process from the mediastinum outwards and to the apices. Ludwig Pick (1933) states that in fresh specimens the Gaucher cells are homogeneous, opaque, and dull hyaline in appearance. With the Mallory stain, with acid-fuchsine, and aniline-blue-orange G, and with previous fixation with picric acid and ammonium bichromate, they appear a light blue, and under higher magnification show, in their cytoplasm, an irregular network, bound like spider webs with the finest thread-like fibrils. Through these the cytoplasm appears wrinkled rather than foamy or roundly vacuolated. The wrinkles correspond to the remains of the spongioplasm in the meshes of which the Gaucher substance is stored. Large cells with this type of cytoplasm are found in no other affection. The cells measure from 20 to 80 μ in their largest diameter; they are polymorphous, and are often furnished with projections. The nuclei are either single or multiple, and not infrequently are quite numerous (there were twenty-one in one cell). They are mostly pyknotic. In those cells where there is a single nucleus it is often eccentric in position, generally near the cell border. Mitoses are disputed. Pick found arterial branches within the nests of Gaucher cells.

TEMPORARY POSTPONEMENT OF MENSTRUATION BY OESTRADIOL BENZOATE

BY

GEORGE L. FOSS, M.A., B.Ch.Camb.

Colston Research Fellow; Clinical Assistant to the Gynaecological Department, Bristol Royal Infirmary

(WITH SPECIAL PLATE)

There are occasions when a temporary postponement of menstruation would be a great advantage. I refer to such times as athletic championships, examinations, and weddings, when a condition of bodily comfort and peace of mind is essential, and this cannot be if these events coincide with menstruation. In such cases I suggest that the delay of menstrual bleeding for a few days or a week is a justifiable therapeutic measure on a few special occasions of a woman's life; but I do not think it is a practice to be carried out more than once or twice during an individual lifetime, as it may be unwise to upset the normal delicate pituitary-ovarian rhythm too frequently.

The idea of such therapy arose from the treatment of some of a series of cases with oestradiol benzoate.* It was found that if injections were carried out through the whole cycle the next bleeding was delayed or even inhibited. In some cases of oligomenorrhoea and hypomenorrhoea treatment was sometimes followed by a short period of amenorrhoea. In such cases bleeding might be delayed if injections of 10,000 I.B.U. were repeated, whereas in patients with normal loss this occurred if dosage was raised to 50,000 I.B.U. This is explained by Zuckerman's work (1936) on the production of uterine bleeding by oestrin withdrawal. Cyclical treatment of cases of oligomenorrhoea was not followed by amenorrhoea when 50,000 I.B.U. were given only in the first fifteen days of the cycle.

Zuckerman (1936), working with monkeys, showed definitely that if oestrone is given for a period of fifteen days in a dosage known to be adequate for proliferation, and is then withdrawn, bleeding will occur about seven to eight days later. If this threshold dose is continued throughout the cycle bleeding is postponed for as long as the dose is kept above threshold. If allowed to drop below, either by reducing dosage or by increasing the interval between injections, bleeding would occur. Zuckerman (1936) suggested that if superthreshold doses were given throughout the cycle ovulation was inhibited and the proliferation phase was continued. If injections were started after the middle of the cycle following ovulation it was doubtful whether oestrone would then inhibit bleeding. Evidence was inconclusive on this point even from Zondek's series (1936). If given after the middle of the cycle it was necessary to use much larger doses to cause inhibition. B. Zondek (1936), in the series referred to, noticed that during therapeutic enlargement of hypoplastic uteri of sterile women the next bleeding was often delayed if moderate doses were continued through the

* Oestradiol is six times as physiologically active as oestrone. The standardized preparation used in this work was progynon B oleosum—Schering.

cycle. When started in the first half of the cycle the stage of proliferation is continued, if dosage is greater than threshold value, into one of endometrial hyperplasia and ovulation is inhibited, so that bleeding takes place after oestrin withdrawal from a proliferative phase and not from the usual secretory or premenstrual endometrium. This may be due to inhibition of the anterior pituitary. There is some evidence that even after the corpus luteum is atrophied bleeding does not occur until after withdrawal of oestradiol. Now is it possible to use these facts and theories to delay normal menstruation for social reasons, and is it likely to do any harm? To be a practical success it is a disadvantage for injections to be given every three days throughout the cycle. It is simple to postpone menstruation if 50,000 I.B.U. are given in this way, but injections of 10,000 I.B.U. are not certain in their results, as demonstrated by Cases I and II.

Case I

This woman, aged 22 and married, whose menstrual history was regular every twenty-seven to thirty days, was treated with oestradiol benzoate for intrinsic dysmenorrhoea. First injections of 10,000 I.B.U. given every four days throughout the cycle failed to inhibit bleeding. Following this menstruation the dose was increased to 50,000 I.B.U. throughout the cycle every four days at first, then towards the end of the cycle injections were given on alternate days over a total period of thirty-five days. Seven days after withdrawal bleeding started.

The necessity for injections being nearer together and of large dosage if treatment is started after the fourteenth day was demonstrated in this same case, in which failure occurred in a later attempt when injections were spread out too much.

The irregularity of the menstrual cycles in this case following experimental delay of bleeding was due to treatment for dysmenorrhoea being continued. Trials were given to progesterone at the end of the cycle just prior to menstrual flow, and also to oestradiol benzoate in the second half of the cycle, the details of which are irrelevant and therefore not published in this paper.

Case II

This patient, an unmarried woman aged 22, was treated for intrinsic dysmenorrhoea, and the menstrual history was regular, 4-5/28. The menstrual flow ceased the day before treatment was started. Injections of 50,000 I.B.U. were given twice weekly for thirty-four days and then bleeding started two days later and lasted ten days. The effect was temporary only, and subsequent menstruation was normal.

For practical purposes it is desirable to give injections in the second half of the cycle only, when Zuckerman (1936) was doubtful as to its success owing to the previous occurrence of ovulation. However, I have succeeded in postponing menstrual bleeding for some days after starting injections on the nineteenth day after the cessation of the last bleeding, which was proved by curettage to be from a secretory-phase endometrium. In this case dosage was 100,000 I.B.U., given on alternate days. This is necessary to maintain a high concentration of oestradiol benzoate, which has been shown by Mazer and Israel (1937) to fall four days after an injection. It is therefore necessary to give a large dose and to give it on alternate days. Some idea of the dose which should be necessary can be gauged from the usual menstrual loss expressed in number of diapers and number of days of bleeding. The threshold dose is probably greater in patients with more copious loss.

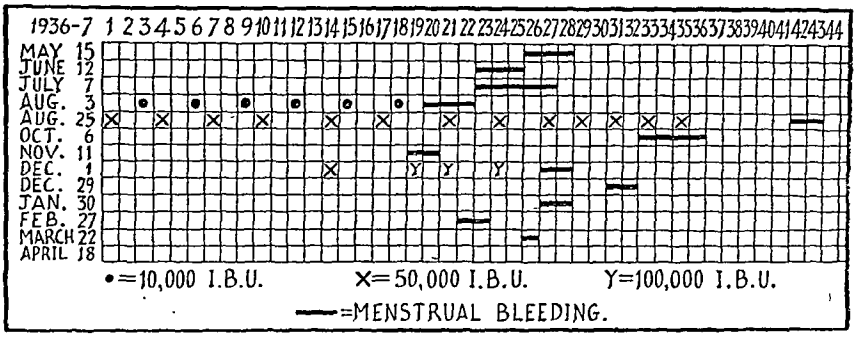

CHART 1.—Menstrual Record of Case I.

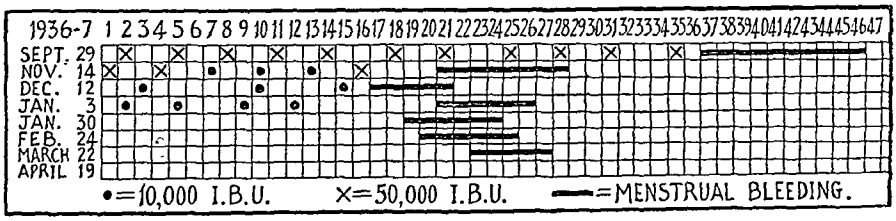

CHART 2.—Menstrual Record of Case II.

Case III

This patient, an unmarried woman aged 32, had been treated for irregular menstruation for seven months with oestradiol benzoate. Her usual cycle varied between twenty-eight and thirty-five days, and when she came for treatment this had lengthened. I selected this case for trial, as menstruation was apparently corrected by treatment and her record of menstrual function was preserved. She was curetted on the first day of bleeding, which was twenty-six days after the last day of the previous menstruation. Ovulation had obviously occurred, as the pathological report showed that she was bleeding from a secretory-phase endometrium. Accordingly nineteen days after this bleeding finished—long after ovulation was thought

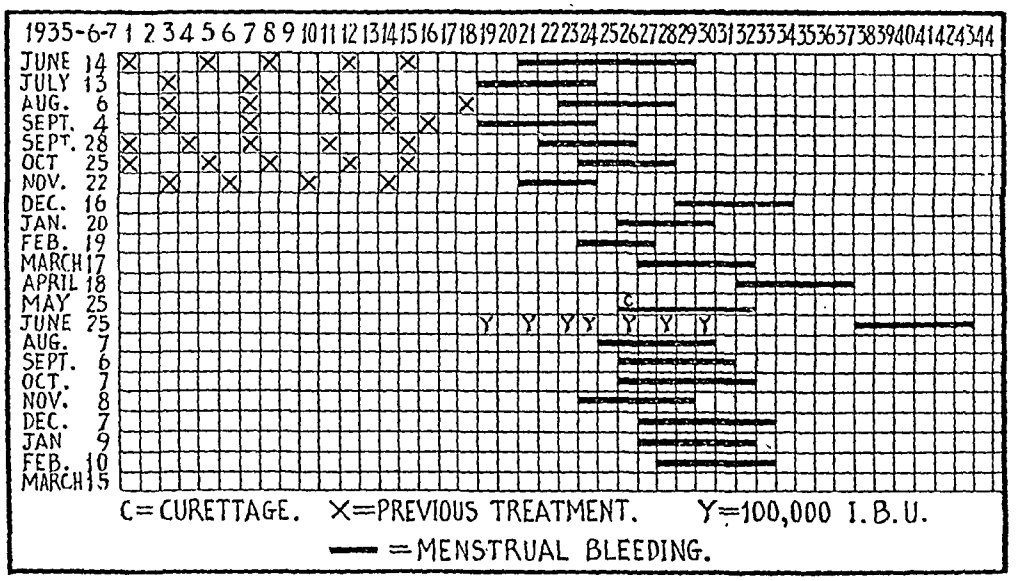

CHART 3.—Menstrual Record of Case III.

to have taken place—I started giving oestradiol benzoate injections. 100,000 I.B.U. were given on alternate days, amounting in twelve days to a total dose of 700,000 I.B.U. Following the withdrawal of oestrin on the thirtieth day of the cycle bleeding occurred eight days later and lasted six days.

This cycle was forty-three days as against thirty days, the average of twenty cycles. It is evident, then, that I succeeded in postponing bleeding for eight days, and treatment had been started at least five days after the probable date of ovulation. No deleterious effect was produced, and it can be seen on referring to the menstrual record that there was no interference with the regularity of the subsequent periods.

The pathologist reported a typical menstrual mucosa with the cytogenic stroma cells showing marked menstrual or decidual reaction (see Plate).

In cases where the menstrual loss is usually slight 50,000 I.B.U. on alternate days, when started after the fourteenth day, is sometimes successful, although it is wiser to give this daily after the first few injections and towards the expected time of onset.

Case IV

An unmarried girl, aged 21 years, previously treated for dysmenorrhoea, was taken for trial, as her menstrual record was particularly regular. This time small dosage was tried, and was again started long after the normal time of ovulation, but in this case I had no record of the endometrium. Injections of 50,000 I.B.U. were begun on the nineteenth day after the cessation of the last bleeding. 200,000 I.B.U. were given in eight days, and this was sufficient to postpone bleeding during the time injections were administered, but it followed two days after the last injection.

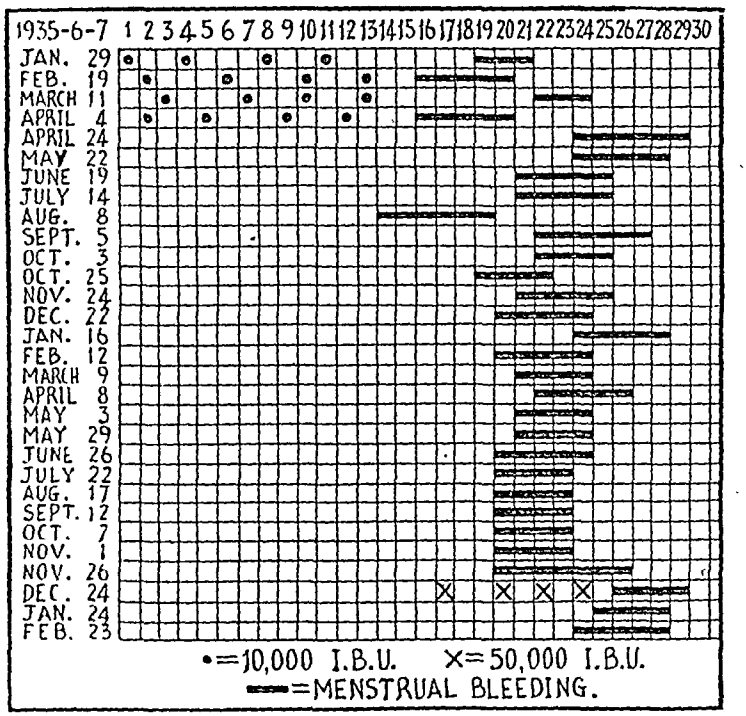

CHART 4.—Menstrual Record of Case IV.

Commentary

Zondek (1936) says that no ill effect was found in his cases, and so far no harmful effects have resulted in any of my series. Occasionally, as in Case I, the subsequent menstruation also is delayed, but usually the normal rhythm returns at once. An occasional postponement of some days does not seem likely to upset the pituitary-ovarian rhythm, as in many people menstruation varies a few days each time. A temporary inhibition of the anterior pituitary by oestrin does not seem deleterious, according to my experience of large doses.

One small point in technique is important. It is essential when injections are given, especially in obese patients, to make certain that there is no leakage from the tissues. The oily solution of oestradiol benzoate should be deeply injected intramuscularly, preferably in the buttock and with the needle in an oblique direction. On withdrawing the needle the skin should be pinched up with the thumb and forefinger of the left hand to approximate firmly the walls of its track. Unless these small points are rigidly observed failures may occur, as there is a tendency for leakage of the oily solution, with consequent drop in dosage. It has the same effect as oestrin withdrawal, or as giving injections at too infrequent intervals, by reducing the level below a threshold value. The essence of this therapy is to maintain a high superthreshold level of oestradiol benzoate until after the time when menstruation is expected.

Summary

1. Postponement of menstruation temporarily is occasionally justifiable.

2. Inhibition of menstruation is simple by continuing therapy with 50,000 I.B.U. throughout the cycle at intervals of three to four days.

3. It is possible to postpone menstruation when injections are started, after ovulation has probably occurred, at about the nineteenth day of the cycle, but dosage must be greater, such as 100,000 I.B.U., and the intervals should be shorter.

4. There are no harmful effects.

5. The technique of injection is of great importance.

Clinical Memoranda

Schamberg's Disease

(WITH SPECIAL PLATE)

In view of its comparative rarity the following case of Schamberg's disease is worth recording.

A Parsee lady of middle age attended the skin clinic of the J.J. Hospital complaining of a peculiar rash on the legs and forearms of about eight months' duration. Apart from the disfigurement the rash caused, there were no subjective symptoms. Careful inquiry elicited that the rash started in the form of minute puncta of bright red colour on the anterior surfaces of both legs immediately below the knees, and gradually spread downwards, involving the upper two-thirds, and also spread to the forearms. The lesions gradually faded, leaving behind a brownish pigmentation which in its turn slowly disappeared, the skin assuming its normal colour. The complete disappearance of the lesions was seen only on a limited area of the skin. A certain amount of telangiectasis was also noticeable (see Plate).

When the patient first came under my observation the disease was fairly well advanced, and coalescence of individual lesions had occurred, leading to the formation of brownish patches. New lesions were still coming out, and a few bright red pinpoint puncta at a distance from the original eruption were present. Apart from the rash clinical examination revealed no other abnormality. Teeth, tonsils, ear, nose, and throat were normal, and no evidence of septic focus was found anywhere. The platelet count was normal and the Wassermann reaction negative.

Schamberg's disease constitutes one of a group of diseases of unknown aetiology which include Majocchi's disease, purpura annularis telangiectodes, and poikilodermia atrophicans vasculare, and which are provisionally classified by some amongst the purpuras. Histological examination shows the chief seat of the disease to be in the subcapillary layer of the corium, where a mild degree of inflammatory reaction and deposition of a pigment—shown by Kingery to be an iron derivative—are present.

I am indebted to Major S. L. Bhatia, I.M.S., for allowing me facilities for taking photographs of the patient.

Craniocleidodysostosis in a Boy of 7

(WITH SPECIAL PLATE)

The history of the case is as follows:

The child was a forceps delivery. He had a moderate degree of hydrocephalus with bulging of the anterior fontanelle. Eight days after delivery there were convulsions, which disappeared in a fortnight.

At the time of writing the boy attends school and appears to possess normal mental faculties consistent with his age. His only symptom is fatigue after walking moderate distances.

Examination revealed the following:

Only one and a half inches of the left clavicle was palpable on its medial end. Of the right clavicle I could only palpate about half an inch of its medial end. No portion of the clavicles was palpable laterally. There was an extremely wide range of movement of the shoulders. Both shoulders could be made to touch anteriorly in the midline. A definite depression about the size of a shilling could be felt in the region of the anterior fontanelle. The base of this depression did not yield to the palpating finger. There were no other abnormalities elsewhere.

X-ray examination revealed a thin cranial vault and displayed a definite depression in the region of the anterior fontanelle. At the base of this depression there was an extremely thin layer of bone. The clavicles appeared as two rudimentary medial ends which were extremely small in proportion to the chest wall.

LÉON FEINSON MULDAVIN, M.R.C.S., L.R.C.P.,
Royal Free Hospital, London. Casualty Officer.

A Case of Calcinosis

(WITH SPECIAL PLATE)

The following report of a case of calcinosis circumscripta may be of interest.

A girl aged 13 years first came under notice on January 27, 1936, and was found to have a fluctuating swelling about the size of a pigeon's egg on the upper and outer side of the right small toe, with the tract of a sinus opening on the sole of the foot and discharging a creamy, chalky-looking substance. Nodules were found on many of the digital joints of both hands, left elbow, and left knee (see Fig. 1, Special Plate), also on the points of some of the fingers. Her family history revealed nothing of interest. There was no tuberculosis, rheumatism, or gouty tendencies, and no history of a similar condition in other members of the family or relatives or friends.

Apart from a minor degree of anaemia and debility her health had been fairly good. She had had a lump, possibly a sebaceous cyst, removed from the scalp in 1933, and a swelling at a finger-joint the same year. This had been incised and the contents expressed. Similar swellings had made their appearance about this time, involving the joints now affected. The swelling on the foot was incised twice, and once the chalky contents were cleared out the wounds healed rapidly, leaving little scarring and no impairment of the joints. The contents of a nodule excised from the left elbow and examined microscopically appeared similar to those of a sebaceous cyst, but the chemical analysis showed a high calcium content. A sebaceous cyst excised from another patient contained no calcium. *X*-ray examination showed dense shadows at the site of the nodules (see Fig. 2)—particularly in the right foot, in both hands, and in the left knee—typical of the condition described as calcinosis circumscripta by Dr. D. W. Brooks in the *Quarterly Journal of Medicine*, July, 1934.

A. P. AGNEW.

Norwich.

Fatal Coronary Thrombosis in a Man Aged 23

(WITH SPECIAL PLATE)

The following case is worthy of record owing to the youth of the patient.

A Tamil manual labourer, while on his way to work at about 7 a.m. on January 4, 1937, complained of severe pain in the chest and left arm, and collapsed. He was attended to at a dispensary and brought to the General Hospital, Colombo. When seen at the out-patients department at 8 a.m. he had pain in the left shoulder and arm, but the symptoms of collapse had passed off. He was admitted under my care, and reached the ward in a moribund condition, with cold, clammy extremities and imperceptible pulse. He died at 8.25 a.m.

No history of previous rheumatic fever or heart disease could be obtained. A diagnosis of coronary thrombosis was suggested, and a post-mortem examination was made by the Judicial Medical Officer of Colombo, Dr. N. Sinnadurai, who has supplied me with the enclosed photograph and the following note on the appearance of the heart.

"The left ventricle showed globular dilatation. The valves were intact and the musculature appeared healthy to the naked eye. In the beginning of the descending branch of the left coronary artery of the heart there was an ante-mortem thrombus about a quarter of an inch long, attached to the wall of the vessel. The distal portions of the vessel below the thrombus showed whitish atheromatous plaques. There were similar plaques also in the right coronary artery. Death was due to coronary thrombosis."

In 1935 a case of coronary thrombosis with recovery in a patient aged 24 years was reported from the wards of the late Dr. E. Garvin Mack by Dr. P. B. Fernando, medical registrar of the General Hospital, and an account of it was given in this *Journal* (1935, **1**, 976). The present case, as far as I am aware, is the youngest on record, since this patient was born on January 3, 1914, and was therefore 23 years and 1 day old at the time of his death.

JOHN R. BLAZÉ, M.D., M.R.C.P.,
Colombo. Senior Physician, General Hospital,

An Obscure Case of B. Coli Peritonitis

This case, that of a girl aged 5 years, one of female twins, first came under notice at 8 p.m. on October 1, 1936. The history was as follows:

CASE HISTORY

The child complained of abdominal pain while out walking the previous day, about midday, and vomited. She was taken home and put to bed, and her condition improved, although slight pain in the region of the umbilicus persisted. She vomited a second time after an evening meal of bread-and-milk. The temperature was taken by the mother, an ex-surgical sister of a London teaching hospital, and was found to be normal. The child had an undisturbed night and slept well. The next day she seemed fairly well but still complained of slight abdominal pain, and the mother administered a dose of castor oil, resulting in an offensive yellow fluid stool. The pain persisted, and although the temperature remained normal it was decided to have medical advice. On cross-examination of the mother it was elicited that the child had been passing offensive stools for some days, and that for the past year or two the breath had on occasions been offensive. There was no history of worms, and the patient had previously been perfectly healthy. On examination the temperature was found to be 98.4° F.; the pulse was 120. The child was pale but bright and composed. There was slight rigidity of the right side of the abdomen and a little tenderness in the right iliac fossa. The tongue was furred.

The patient was removed to the Chesham Cottage Hospital, and after consultation it was decided to perform appendicectomy. The abdomen was opened by a muscle-splitting technique. The appendix when exposed to view showed only a slight thickening of the tip and a little injection of the superficial capillaries. There was no exudate and no sign of peritonitis. The appendix was removed and the stump invaginated in the routine manner. The abdomen was closed without drainage. On opening the appendix it was found to contain numerous threadworms and a little offensive pus; there were also a number of submucosal haemorrhages. The child did well for a week following the operation, but occasionally complained of a little pain in the region of the wound. She continued to pass very offensive pale yellow fluid stools.

About six o'clock, however, on October 8 she complained of severe generalized abdominal pain. The temperature rose to 101° F., and the pulse to 130. On examination there was general rigidity of the abdominal wall and tenderness, which appeared to be most severe over the descending colon. The operation wound was clean and healing normally. A blood count showed 15,000 leucocytes, of which 89 per cent. were polymorphonuclear leucocytes. It was decided to reopen the abdomen, and this was done through a right paramedian incision. The small intestine and omentum were found to be intensely injected, and about an ounce and a half of thin greenish-yellow odourless pus was evacuated. There was no evidence whatever of any infection from the site of the appendix operation, and the wound was soundly healed. No perforation of the intestines was discovered. A specimen of the pus was obtained and the abdomen was closed; two drainage tubes were inserted into the lower part of the wound reaching well down into the pelvis. The child has since made an uneventful recovery, and there has been no trace of threadworms in any of the stools, which have ceased to be offensive. The pus obtained from the abdomen grew a pure culture of *B. coli*. Agglutinations of serum against typhoid and paratyphoid A and B were negative.

DISCUSSION

The case would appear to present one or two unusual features. In the first place the mother, a woman of considerable nursing experience, was positive that the child had never passed any threadworms, and quite certainly no threadworms were passed in hospital. Secondly, it seems difficult to account for the presence of sufficient numbers of *B. coli* in the peritoneal cavity to cause a general peritonitis a full week after the removal of the appendix. If the peritoneum had become contaminated during the first operation, which seems very unlikely, it is hard to imagine why the onset of the peritonitis was delayed. As previously stated, there was no evidence at the second operation of the trouble arising from a leakage from the appendix stump.

It is well known that in children pneumococcal peritonitis may develop as a secondary manifestation to pneumonia complicated by empyema, and streptococcal septicaemia may be complicated by acute peritonitis, the infection being conveyed by the blood stream. In this case of diffuse *B. coli* peritonitis no precise focus of infection could be found surgically, but it is established that the child was passing extremely offensive stools prior to the development of peritonitis, and it is probably correct to conclude that (1) an intense *B. coli* infection was present in the colon, and (2) that a secondary *B. coli* peritonitis supervened, either via the blood stream or else by direct permeation through the walls of the colon.

W. B. GABRIEL, F.R.C.S.

Reviews

CALMETTE'S BOOK ON TUBERCULOSIS

L'Infection Bacillaire et la Tuberculose chez l'Homme et chez les Animaux. By A. Calmette. Fourth edition, revised by A. Boquet and L. Nègre. (Pp. 1,025; 70 figures, 24 coloured plates. Broché, 150 fr.; cartonné toile, 175 fr.) Paris: Masson et Cie. 1936.

Though first published as recently as 1920, Calmette's monumental book can be termed a classic in tuberculosis literature. A second edition appeared in 1922, followed by a third in 1928, and an English translation of the former was published in 1923. The last nine years have witnessed much work and controversy on certain pathological aspects of tuberculosis; the fourth edition, just issued, is therefore timely. The death of Calmette in 1932 left the task of revision to be done by Boquet and Nègre, heads of departments in the Pasteur Institute and collaborators of Calmette in the previous edition. It was inevitable that the wish to retain the spirit of the original author and the structure laid down by him should have induced Boquet and Nègre to avoid making drastic changes, changes that would have greatly increased the value of the book. This applies particularly to views held by Calmette in the face of much opposition. Thus the section on B.C.G. vaccination is hardly altered; too little note is taken of the work criticizing the method, and the lack of thorough revision is seen in the following:

"In July, 1921, a first infant fatally destined to tuberculous infection by reason of its inevitable cohabitation with a phthisical grandmother, ingested three doses, on the third, fifth, and seventh day after birth, of 2 mg. of B.C.G. each time (totalling 6 mg., or 240 million bacilli). No untoward incident followed. This child, though brought up in an infected environment, has developed normally. *It is now five and a half years old* [reviewer's italics] and remains in perfect health."

On the other hand, it is good to note the more cautious attitude adopted in regard to the filterable form of the tubercle virus. In fact, the term "ultravirus" no longer appears in the index. Special chapters of this edition are devoted to culture on sympathetic media, to dissociation, to the avian type of the bacillus, to spontaneous tuberculosis in rabbits and guinea-pigs; and some chapters are much fuller—for instance, that dealing with the chemical constitution of the bacillus. The book contains an enormous amount of information, and the best parts are those concerned with purely bacteriological aspects. The section on morbid anatomy, as in the third edition, is sketchy, and in it is ignored the most recent work of German authors, work that has thrown much light on the evolution of pulmonary tuberculosis. Indeed, in the whole book there is too great a tendency to favour French authors, even when their work has not withstood criticism from elsewhere.

Many hundreds of references are given; nevertheless statements are often made without mentioning their source. Thus we should be interested to know when "in London G. Lissant Cox and A. Salusbury MacNalty of the Ministry of Health have found, in one dispensary alone, a mortality of 22 per cent." (0 to 1 year—in children born of tuberculous mothers, remaining in contact with the mothers, under the supervision of health visitors). The usefulness of the book is, moreover, much diminished by the absence of an index of personal names.

The controversy round B.C.G. and the "ultravirus" should not make us forget the excellent work done by Calmette on other aspects of tuberculosis; and the book can therefore be recommended to those who will be able to separate the wheat from the chaff.

NATIONAL INTELLIGENCE

The Fight for our National Intelligence. By Raymond B. Cattell, M.A., B.Sc., Ph.D. With introductions by Lord Horder, Major Darwin, and F. P. Armitage. (Pp. 166. 8s. 6d. net.) London: P. S. King and Son. 1937.

Population, physique, intelligence, character, present four of the major problems of Western civilization which are at last beginning to attract national attention in this country. They are not really separable problems, but parts of one whole; each calls for a good deal of attention to the others. Yet a full study of that whole, however enhanced in value by its comprehensiveness, is still awaited and is bound to be bulky, and any serious consideration of one of its parts can meanwhile be welcomed. Such consideration of the subject of national intelligence is contained in a portion—far too small a portion—of Dr. Raymond Cattell's book. It is a serious study in that it describes a painstaking psychological and statistical investigation of intelligence in a limited population in definite areas, alleged to be typical. It has the merit, too, of not ignoring altogether, as some inquiries have done, the question of population decline and of character as distinguished from intelligence. But, as the author himself points out, the inquiry depended upon "the unaided efforts of a single investigator," and was "limited to a total expenditure of £250." Under these conditions testing was confined to 10-year-old children only, and these in but 3,734 families. Controls were lacking. Doubtless it was not possible to do much more, but these are very meagre materials on which to base the dogmatic and far-reaching conclusions to which the investigator invites us. There is another inquiry now proceeding of a not dissimilar character, but with ampler means and of a more comprehensive and scientific nature, and it would be wise to suspend judgement at least until the results of this are published.

The very title of the book suggests a bias. There are no fewer than five introductions, including the author's own "foreword" and his first chapter entitled "The Twilight of Western Civilization?" Lord Horder's introduction is commendatory but careful. "Assuming no fallacies to be present," he says, "the evidence seems overwhelming." Yet he speaks of Dr. Cattell's "discovery" and strains credulity when he claims that "careful perusal of the conditions of the research and of the argument does not reveal any obvious fallacy in either." Major Leonard Darwin begins with an absurdity—"It has been conclusively proved by many inquiries that for many years past the average child has been living in a worse home than the average parent"—and continues with a clear *non sequitur* in the majority of his paragraphs. Mr. F. P. Armitage assumes as postulates statements clamouring for discussion; and the author himself discloses a tendency to find only what he sought, and to square conclusions with his preconceptions. But if the book be read throughout in a cautious and alertly critical spirit much of it will be of value. Its facts are helpful, though by no means conclusive. Its arguments are well stated, though often specious. Its inference that our national intelligence has, since about 1875, been rapidly decreasing through a differential birth rate, whereas up to that time it had been increasing through a differential death rate, is not established. The remedies suggested for such decline as there may be are perhaps more moderately stated than would

gical remedy, if Dr. Cattell's statements are accepted face value, would be the compulsory sterilization whole of the "subcultural" or "social problem" in which he sometimes seems to include most of mentary school children; whereas he would rely upon universal knowledge and practice of birth . He is wise enough, however, in addition, to e the positive and active encouragement of mater- nong those of higher intelligence to the extent of s of three or four children, and to urge that psycho- as well as economic means should be used to l.

Cattell points out that "no service is done by ating or indulging in the prophecies of a scare- ." It seems inconsistent to follow this with the n that "through a *complete* practice of birth , extending to the lowermost sections of the popula- ankind could leave behind for ever, within the f this century, the aimless suffering, the vacillating e, and chronic relapses which have characterized ion since the culture of Sumeria first blossomed."

HAEMODYNAMICS

ology and Pathology of the Heart and Blood ls. By John Plesch, M.D., L.R.C.P. & S.Ed. (Pp. 15 figures. 15s. net.) London: H. Milford, Oxford ersity Press. 1937.

nn Plesch, author of this work on the heart and vessels, dedicated to his friend Albert Einstein, is ed as professor of internal medicine in the Univer- Berlin without any qualifications such as emeritus rmerly." He has written much, and the present , which is described as a development of his *dynamische Studien*, published in 1909, is divided o almost equal parts—on the physiological and gical aspects—being intended for practitioners as for physiologists. It illustrates the importance value of the application of the ancillary sciences, instance haemodynamics, to medicine. But for inary medical man "the fundamental mathematical ae" to which he is at once introduced in the first may present a somewhat formidable proposition. wever this may be, a diagram explaining the venous es in different positions—the erect and recumbent s—clearly illustrates in the same chapter the l remarks on the avoidance of air-embolism in the of intracranial operations.

blood volume and the less-known distribution of n the various vascular areas are passed in review. ttention is paid to the capillary circulation. Very t estimates of the absolute capillary blood volume en given: the author arrives at this figure by sub- from the total blood volume of four and a half he estimated capacity of the remainder of the ascular system. The flow of blood through the ies is "turbulent," the particles pursuing an r path without any fixed relation to the axis of eam and in contrast to a "laminary" flow. The of open capillaries is regulated by the metabolic of the tissues; thus in toxic goitre the raised lic rate dilates the blood capillaries so as to the diastolic pressure 15 to 25 mm. Hg below its level. The problems of blood pressure receive nsideration, and it is suggested that general atten- as not been directed to the characteristic rise of c pressure in hypertension due to renal disease. loubt is expressed about the site of the responsible the kidneys rather than in the general periphery.

In the section on chronic diastolic insufficiency or "decompensation" it is pointed out that the term cardiac decompensation is not infrequently applied to cases in which the responsible factor is not in the heart. Although the author insists that the common disorders of the circulation can be explained on a mechanical basis without reference to lesions of the cardiac valves, he devotes the last chapter to a critical analysis of the orthodox views of valvular disease. This is an authoritative and thought-stimulating book by one who has devoted much time and thought to the subject.

EPIDEMIOLOGICAL STUDIES

Seuchenentstehung und Klimaforschung, and *Die Entstehungsursachen der Haffkrankheit.* By Dr. med. Friedrich Wolter. (RM. 3.75 and RM. 4.50.) Stuttgart: Hippokrates Verlag. 1936.

Dr. F. Wolter, director of the Hamburg Institute for the Study of Epidemiology, in two recent brochures, volumes 5 and 7 of the series Kleine Hippokrates-Bücherei, continues his travels along paths first broken by Pettenkofer. In volume 5 he seeks to bring epidemiological happenings into relation with the long- and short-waved climatological movements postulated by Brückner. As will be remembered, the late Sir William Hamer was an enthusiastic student of Brückner cycles, and there is no reason to doubt that work in this field is of importance. At its present stage the papers seem rather suggestive than convincing—perhaps because the workers are few and precise numerical data scanty.

Volume 7 deals with a more sharply defined problem—namely, the nature and origin of the remarkable epidemics christened *Haffkrankheit*, which mainly affected fishermen on the Frisches Haff, a narrow gulf communicating with the Baltic and in the neighbourhood of the cities of Königsberg and Danzig; in 1924 there were 600 cases with six deaths, in 1925, 176 with five deaths. The symptomatology of the illness closely resembles that of the better-known epidemic myalgia, but the general opinion in Germany has been that the origin was a form of fish poisoning. Dr. Wolter, however, identifies the new epidemics with an outbreak of 1529 in the Gulf of Stettin, and, as the Frisches Haff is heavily polluted by sewage and factory outflows, finds a basis for subsoil action. His arguments may not be wholly convincing, but the facts cited are suggestive.

THE CLINICAL PSYCHOLOGY OF CHILDREN

Clinical Psychology. A Handbook of Children's Behavior Problems. By C. M. Louttit. (Pp. 695; illustrated. 12s. 6d. net.) New York and London: Harper and Brothers. 1936.

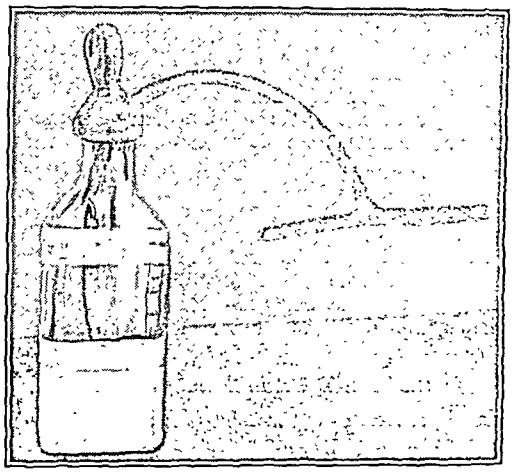
When the author of this book was obliged some years ago to plan a teaching course in what is called clinical psychology he found its scope difficult to define. Clinical psychologists deal with all kinds of activities from the devising of mental tests to deep analysis, with patients of all ages, with problems of child training, delinquency, mental deficiency, mental disease, vocational guidance, and a hundred others. He found no single book which gave a systematic survey of the whole subject. Books which purported to deal with psychology in general were deeply tainted with bias, and none gave an adequate idea of the vast field of specialized books and papers that now exists. He has therefore tried to meet this need, and he has very fairly succeeded—surprisingly, considering the handy size of his book.

He begins by suggesting practical methods for history-taking, examination, and psychometry, and then deals in the remaining three parts of the book with three broad classes of problems: those correlated with abilities and with organic disabilities, and problems of behaviour. One important consideration which governs his approach is that clinical psychology goes far beyond psychology as a science, and the work of the clinical psychologist is intimately bound up also with medicine, education, and sociology; he deplores the absence of any academic curriculum which gives the student a grounding in even the broad essentials of these sciences. He confines the book to the problems of children, because he regards the psychology of the child as the very foundation of adult psychology and the reactions of the child as the foundation of adult behaviour. Although he has been severely restricted in his compass he boldly introduces concrete examples on every page, and the student will probably learn as much from this book as from any other single work that has appeared recently.

Notes on Books

Quelques Verités Premières (Ou Soi-Disant Telles) en Pneumologie Clinique, by Professor EMILE SERGENT (Masson, 24 fr.), is one of a series on various branches of medicine and surgery published under the general editorship of Professors Ombrédanne and Fiessinger of Paris. The intriguing title which, except for the name of the branch discussed, is common to the whole series is explained in the preface written by the editors. Their aim is to give the readers the essential clinical and therapeutic facts which can *at present* be considered as definitely established. Their choice of Professor Sergent for the volume on diseases of the lungs was a happy one. The result is a collection of statements, aphorisms, and counsels based on extensive clinical experience from which the human element is never dissociated, which is written in a style that attracts the reader and emphasizes where emphasis is needed. The following is a good example: "Though the first impression is *often* the best, it is unreasonable to bow down before the aphorism which insists that it should *always* be the best." There is, however, a fly in the ointment. The book is very attractively produced, but the type appears to have been chosen without any regard to reading comfort. The text is wholly in italics, ordinary type being used for certain terms and for emphasis; and even this is carried out somewhat at haphazard.

In the biography entitled *The Life and Convictions of William Sydney Thayer, Physician* (Oxford University Press, 10s. 6d.), Mrs. EDITH GITTINGS REID, the author of a life of Sir William Osler, has given a sympathetic account of Osler's successor in the chair of medicine at Johns Hopkins University, with numerous extracts from his diaries and correspondence. In addition to relating his activities at Johns Hopkins, where his principal contributions to medicine dealt with malaria, typhoid, and bacterial endocarditis, Mrs. Reid gives a vivid account of his experiences and hairbreadth escapes as a member of the Red Cross Mission to Russia in 1917 and as a consultant in the following year to the American Expeditionary Force in France. Thayer was well known in this country, where he was made orator and gold medallist at the Bright Centenary celebration, Foreign Honorary Fellow of the Association of Physicians, and LL.D. of the University of Edinburgh. In France he delivered an address at the Sorbonne in 1923 on "The Contribution of Pasteur to Medicine," and was elected on that occasion Officer of the Legion of Honour and four years later Commander. He was also Laennec Lecturer and Doctor *honoris causa* of the University of Paris and co-editor of the *Archives des Maladies du Cœur*. The text is accompanied by striking portraits of Thayer as professor, military consultant, and amateur fisherman.



Those who wish to keep abreast with current medical literature will be interested to know that this can be obtained from a new publication, *Current Titles from Biological Journals*, edited by L. R. KUHN of the University of Chicago. It is issued monthly, and can be obtained on application to 5603, Drexel Avenue, Chicago, Illinois, the subscription being 1.50 dollars for the remaining months of 1937. This monthly reproduces the main contents of many of the principal biological journals of the world, and medical periodicals are well represented.

Preparations and Appliances

CONTINUOUS BILIARY DRAINAGE

Mr. MALCOLM H. V. CAMERON, F.A.C.S., F.R.C.S.Can., writes from Toronto:

One of the minor difficulties of biliary drainage by means of the T-tube is in the management of the bottle used to collect the bile. A long tube to a container outside the bed hampers the patient's movement, and an open bottle attached to the abdominal binder may easily be spilled, or if used by an

ambulatory patient can only be handled with considerable inconvenience. A stoppered bottle cannot be employed, as the drainage must not be opposed by pressure greater than that of the atmosphere. For the past five years I have overcome these difficulties with the simple apparatus illustrated herewith. An ordinary flat dispensing bottle of three- or four-ounce capacity is provided with a sling made of adhesive plaster folded on itself for about three inches at the top and applied along one side, the bottom, and part of the other side of the bottle. This may be pinned to the binder in the case of a patient in bed, or attached to a bandage about the neck if he be up and about. To prevent side-sway the binder is turned up to as to form a pocket in which the lower end of the bottle rests. A nursery feeding nipple is stretched over the neck of the bottle, and the external arm of the T-tube is brought through it by way of a small lateral slit which forms a watertight junction. The tiny hole at the apex of the nipple permits equalization of pressure, and should the bottle be accidentally inverted allows only a drop or two of bile to escape. Soiling of clothing or bedding is prevented, and the patient is free to assume any comfortable posture in bed, or while sitting or walking. Emptying and cleaning the bottle does not disturb the dressings or incommode the patient.

AN ESTIMATE OF THE INCIDENCE OF DEFECTIVE HEARING IN ENGLAND AND WALES

WITH SPECIAL REFERENCE TO A DEAF PERSONS ACT

BY

ARTHUR G. WELLS, B.S., M.B., D.P.H., F.R.C.S.

It is, I think, commonly agreed among those interested in the problems of the so-called "deaf" that so far insufficient attention has been paid to this unfortunate class of sufferers by the State, and that justice will not have been done until at least equal consideration and provision has been made for them as for their fellow sufferers—the "blind."

Efforts there have been to put forward a Deaf Persons Bill, and a considerable amount of support has been promised by individual Members of Parliament, but it would appear that the Minister is unwilling to do anything in the matter unless the idea has the backing of local authorities. While, however, local authorities accepted one clause in the Bill—namely, the lowering of the school age for the deaf—they could not see their way to support the Bill as a whole.

As I understand it, their main reason was the unknown magnitude of the problem. They had no idea of the numbers involved and consequently of the nature of the cost, and without this knowledge, which has never been forthcoming, they refused their support. In order to give some idea of the size of the problem I have endeavoured to make an estimate, from the results of my own experience and the available data to hand, of the probable numbers who would come within the scope of a Deaf Persons Act, and, secondly, of the approximate number of people with defective hearing in England and Wales. While it would be quite impossible to make any accurate statement or estimate of the numbers in each of these groups one might reasonably estimate a maximum within which they would fall, and this I attempt to do in this paper.

Grades of Defect in School Children

For the purposes of my examinations of school children with defective hearing I divide them into Grades I, II, and III, and Grade II is subdivided into Grade IIa and IIb.

Grade I.—This grade covers children who can hear and understand the conversational voice at twenty feet or over in ordinary class-room conditions. Their hearing loss by the gramophone audiometer test is up to about 15 decibels, and with the pure-tone audiometer 35 decibels. They can benefit by education in an ordinary elementary school. This grade includes also some children with greater hearing loss but whose speech and language development is good and who lip-read well.

Grade II.—These children hear and understand the ordinary conversational voice at between 20 ft. and 2 ft. Their hearing loss with the gramophone audiometer test is between 15 and 40 decibels, and with the pure-tone audiometer between 35 and 60 decibels. By reason of their defect they cannot be properly educated without special arrangements or educational facilities. This group is subdivided into Grade IIa and IIb. Those children coming under Grade IIa can be educated in the ordinary school if special facilities are provided, such as a favourable position in the class, etc. Those in Grade IIb require special school education, but not that necessary with the severely deaf. In this grade also come those children whose hearing defect is worse than that described above but whose speech and language are not seriously affected.

Grade III.—Children in this grade can hear and understand the conversational voice at not more than 2 feet if at all, though they may be able to hear vowels with or without discrimination at greater distances than 2 feet. Their hearing loss by gramophone audiometer test is 40 decibels, and it is over 60 decibels with the pure-tone audiometer. Their speech and language are seriously defective, and they require methods of teaching applicable to deaf children who have not acquired speech and language naturally. This grade does not include any children whose speech and language development is not seriously defective.

It is clear that the persons who would fall within the scope of a Deaf Persons Act would be those who would come under the hearing qualifications of Grade IIb and Grade III.

Regular testing of hearing in the ordinary schools by gramophone audiometer has been established in London for some years, and many thousands of children have been tested. As a result of these tests a certain number have been discovered whose hearing is defective enough to call for education in a "hard of hearing" class, and others who require special facilities in class in the ordinary schools—these being in addition to those found by the routine methods of inspection.

Incidence of Defective Hearing

It has for some time past been generally accepted that the number of "deaf and dumb" in England and Wales is round about 40,000, or 1 in every 1,000.

In the year 1935 the total population of England and Wales was 40,645,000. Of this number 2,834,000 were children of the pre-school period; 5,468,960 were children of the school period; 32,342,040 were people of the post-school period, of whom there are about 3,300,000 of the age of 65 and over.

Roughly the ratio between them is pre-school : school : post-school as 1 : 2 : 11; or, in other words, the pre-school individual constitutes one-fourteenth of the total population, the school individual two-fourteenths, and the post-school eleven-fourteenths.

Let us consider, first, the so-called deaf. In 1935 there were 446 deaf children in the London County Council schools, but of these ninety-four were out-county children. There were in addition forty-five London children in out-county residential schools. Making allowance for these we get a net result of 397 London deaf children.

These 397 deaf children were part of a school population of 534,500; and if these figures are applied to the whole population we arrive at 32,060 as representing the total number of deaf in England and Wales. Further, if these 32,060 are divided up according to the ratio 1 : 2 : 11, it is found that 2,290 are of pre-school period, 4,580 of school period, and 25,190 of post-school period. In arriving at these figures it is assumed not only that those of London apply to the rest of the country but that the incidence in school children is the same as that in pre-school and post-school groups. Is this assumption justifiable?

As far as the first assumption is concerned the Board of Education, from the returns made in 1935, gives 3,291 as the number of deaf children in the country or 0.67 per 1,000 of the school population in average attendance. This figure applied to the whole population would give the total number of deaf as 24,451. I am not at all sure, however, that the returns made to the Board are as reliable as they might be. Further, the work in London is done very carefully and thoroughly, and the figures are sufficiently large—namely, one-tenth of the country—to form a reliable basis for this assumption.

Then as regards the second assumption—namely, that the incidence in the pre-school, school, and post-school groups is the same—I think it is legitimate to accept this, for there is nothing in the post-school period of such consequence as to increase the incidence above that of the school period; and as between the pre-school and school periods the only factor which has to be considered is a post-natal cause of deafness. The only causes worth mentioning in this class of deaf person are meningitis and congenital syphilis. As regards meningitis by far the greatest number of cases are found in pre-school children, and therefore the incidence is hardly altered; while with congenital syphilis most of these cases occur in the first year or two of life, and only rarely are the manifestations delayed until the school period. There are some adults who become extremely deaf, but these I would prefer to classify with the so-called "deafened." On these assumptions we may reasonably accept this figure as being not very far from correct, and therefore no adjustments need be made in these ratios.

As to the cases of acquired deafness—those frequently spoken of as the deafened—the matter becomes rather more complicated, for reasons which I will go into later. There were 210 so-called "partially deaf"—that is, Grade IIb children—in the special schools in 1935. Of this number there were eight out-county children attending the London schools, and one London child in an out-county residential school. Making allowance for these we get a net result of 203 London school children, and, as before, these were found in a school population of 534,500. If these figures are applied to the whole population a rough figure is obtained of 15,436 persons of the Grade IIb type of hearing defect.

In addition to these, however, approximately 30,000 children were tested by means of the gramophone audiometer, and among these were found four children of the Grade IIb type, four of the Grade IIa type, and 34 of the Grade I type. If these figures are applied to the whole population they would represent roughly 5,800 Grade IIb, in addition to the above 15,436 already accounted for; 5,800 Grade IIa type; and 50,000 Grade I type. This would mean that altogether there would be about 21,000 of the Grade IIb type in the country.

As before, it is assumed that the London figures can be applied to the whole of England and Wales. But it cannot be assumed in this case, as was done in the case of the "deaf," that the incidence is the same in the pre-school, school, and post-school periods. Factors arise which make the incidence of hearing defect in post-school life higher than in school life.

Factors Influencing Deafness

There are several factors which influence the incidence of hearing defect in the different groups; chief among these are the hearing defects arising from chronic middle-ear catarrh and otosclerosis; the defect of hearing arising in the course of certain occupations, such as those of cotton-weaving, riveters, boiler-makers, etc.; and senile hearing defect. It will be noticed that though chronic middle-ear catarrh is found among children, it is more common and more pronounced in adult life, while the other factors arise in adult life only. These combine to make the incidence in the post-school group higher than in the school and pre-school. The great difficulty is to get enough evidence to know what the increase is.

Taking the noisy trades, it is well known that the incidence of defective hearing among the cotton-weavers of Lancashire is very high, and it also is with the wool-weavers. Riveters and those in the boiler-making trade have long been known to develop hearing defect as the result of the continuous loud noise associated with their work. Some time ago Dr. G. P. Crowden examined a number of these workers audiometrically at Devonport, and he found an incidence of 33 per cent. defective hearing among the riveters and boiler-makers, but among other workers not engaged in the noisy branches the incidence was about the same as that in the case of school children. I propose, therefore, to suggest 33 per cent. as the figure of incidence of defective hearing among the noisy trades generally, and I think one-third would be a liberal estimate of those who are affected severely enough to come within the scope of a Deaf Persons Act. The number of workers in noisy trades is 315,300. So on this basis those with defective hearing would total 105,100; and those severely affected roughly 35,000.

Deafness in Later Life

With regard to the deafness of later life—that is, 65 years and over—I have made audiometric tests in some of the public institutions. There are 180,295 persons in the public assistance institutions, and of these 61,549 are over 65 years of age. About 76 per cent. of these persons failed to pass the tests, and roughly 20 per cent. came within the type of Grade IIb. This figure applied to the whole population of persons over 65 years—that is, roughly 3,000,000—gives us 2,288,135 as defective in hearing and 593,220 of the Grade IIb type. These inmates of public assistance institutions, as is well known, are mainly below average in intelligence, etc., and so the figure is probably rather on the high side.

With regard to the people of the post-school group up to 65 years of age I have made tests of some hundreds of individuals in Government offices, public assistance institutions, etc. This combination contained both the best type of individual, the poorest, and the intermediate, so all sorts are included.

The result of my tests showed that about 12 per cent. failed; but I was rather surprised to find that there was not a single case of the Grade IIb type among them. Many were severely deaf in one ear, but not in both. No doubt some cases would be met with if considerably larger numbers were tested, but if we triple the incidence of the Grade IIb as found by the audiometric test in the school period (that is, an extra 8 per 23,038 for this group) an adequate allowance will have been made for chronic middle-ear catarrh, etc., especially in view of the liberal allowance made for the noisy trades and the figures given for the over 65 years group. If then the available data are collected and the necessary adjustments made the following figures are obtained.

Table giving numbers of those with Defective Hearing

1.	Grade III type		32,050
2.	Grade IIb type (based on those not audiometrically tested)		15,436
3.	Noisy trades (33 per cent. of 315,300)		105,100
4.	Deafness among those 65 years and over		2,288,135
5.	8 per cent. failures audiometrically tested applied to pre-school children (3,000,000)		240,000
6.	8 per cent. failures school children (5,500,000)	440,000	
	Less 20 per cent. passed after treatment	88,000	352,000
7.	12 per cent. failures post-school period up to 65 years (29,000,000)	3,480,000	
	Adjustment for noisy trades already accounted for —Deduct 12 per cent. of 315,300	37,836	3,442,164
	Total		6,474,885

The number thus amounts roughly to 6½ millions, or about 16 per cent. of the population or 1 in 6 persons.

Though these people are from a medical point of view defective in hearing, quite a large proportion of them have only a comparatively slight defect, and, further, many have a defect in one ear only. For example, in the case of the school children roughly two-thirds are defective in one ear and one-third in both ears; so quite a large proportion of this huge number have little or no handicap. Further, if all cases that would benefit from treatment were treated efficiently the number would not be so high.

To make an estimate of the number of persons who would be covered by a Deaf Persons Act, a list must first be made of all those of Grade III and Grade IIb types.

1.	Grade III type		32,060
2.	Grade II*b* type based on those not audiometrically tested in school		15,436
3.	Grade II*b* type found by audiometric testing on the basis of 4 per 28,038, applied to the population, which includes the pre-school, school and post-school groups up to the age of 65 years—that is, on a population of 37,000,000		5,349
3*a*.	Allowance for cases of chronic middle-ear catarrh and otosclerosis, etc., for people of the post-school group up to 65 years at the rate of 8 per 28,038=roughly		8,000
4.	Noisy trades Grade II*b* on the basis suggested .. An adjustment must be made here, since these come into headings Nos. 2 and 3; and we must take Nos. 2 and 3 as applied to the post-school population up to 65 years, in which these workers fall; that is, 1 per cent. of 15,151 (203 in 534,500 gives 11,014 in 29 millions; 4 in 28,038 gives 4,137 in 29 millions; that is, 15,151 altogether. 315,100 in about 1 per cent. of 29 millions. ∴ 1 per cent. of 15,151=151) ..	35,000 151	34,849
5.	Grade II*b* deafness occurring in persons over 65 years, which includes senile deafness, advanced middle-ear catarrh, otosclerosis, etc. If results of the tests be applied to the 3,000,000 population the figure would be 593,220. But many of these receive State assistance at the age of 65 years. There are, however, 575,391 who do not receive aid from the State until 70 years of age, and if we apply the results of our tests to these we get a total of 113,773 who would fall within the scope of a Deaf Persons Act between the age of 65 and 70 years ..		113,773
	Giving a total of		209,467
	From this number have to be deducted:		
(*a*)	The Grade II*b* audiometrically tested pre-school and school population—namely, 8,500,000 at the rate of 4 per 28,000	1,214	
(*b*)	The Grade II*b* not audiometrically tested pre-school and school population—namely, 8,500,000 at the rate of 203 per 534,500	3,210	
(*c*)	The Grade III pre-school and school population—namely, 8,500,000 at the rate of 534,500 who would not come under the Act	6,313	
			10,737
	Giving a net result of		198,730

Conclusions

To sum up: if the figures for London are accepted as applicable to the whole population, and the results of the tests of our "samples" of the different groups are applied to the remainder of the population, we arrive at an estimate of about 6½ million people who have defective hearing in one or both ears—that is to say, 16 per cent. of the total population of England and Wales, or one in every six persons.

Also the number that would come within the scope of the benefits of a Deaf Persons Act would be about 198,000. This, however, is a maximum figure, because a very definite proportion would not need to receive benefits under the Act; for example, all those deafened through noisy occupations, so long as they retained their jobs—and they would not lose them on account of their hearing defect. Again, a certain number of those deafened, being in a more affluent position, would not require assistance.

For these reasons the true figure would be more likely to fall in the neighbourhood of 150,000.

This is not exact, of course, but nor would any other method of investigation be. If it were possible to take a census we should not be any better off. The ordinary census is quite a different thing. First, it is compulsory; secondly, the questions to be answered—for example, the number of males and females in the house, etc.—are comparatively easy to answer, but in the case of a census dealing with defective hearing the results would not be worth the paper they were written on. In the first place, it would be voluntary, and many people would not make a return; and, in the second, many would return themselves as normally hearing when they were not. It is a common experience to examine an individual with over 50 per cent. of his hearing gone before he realizes he has a hearing defect at all. Then how would those who regard themselves as defective make their return, and under what heading?

At the present time there is a special committee sitting on the problems of defective hearing, and I have the honour to be on that committee. We have taken the evidence of many witnesses, and I think I should be correct in stating that no two of those witnesses meant just the same thing by the terms "deaf," "partially deaf," "hard of hearing," etc. These are vague and elastic terms, meaning one thing to one person and another thing to another. Their use should be very restricted. This is why I have adopted the terminology of the grades in my examination and classification of school children, each grade being defined exactly.

This method is concise and scientific, and if used by all would make for clear understanding.

If witnesses whose life-work is among the deaf adopt different standards in their minds for these terms it cannot be expected that the "man in the street" would show anything approaching unanimity in his answers. The only possible way to approach accuracy would be to examine the 40 million people in this country, and even then, unless they were examined by one examiner—which of course would be quite out of the question—the personal factor cropping up in the different examiners would make for variations. So even this would not give us an accurate return.

Nevertheless if it is possible to give—as I have attempted to give here—an estimate of the probable number around which the true figure, if known, would fall, a step will have been taken to solve a difficult problem and towards obtaining a Deaf Persons Act.

Summary

1. A rough estimate has been made (*a*) of the total number of persons with defective hearing in England and Wales, (*b*) of the number of persons who would come within the scope of a Deaf Persons Act, on the lines of the Blind Persons Act.

2. No method of investigation of any kind would furnish an accurate figure.

3. The method employed in this investigation was that of applying the incidence found in "samples" of various sections of the population to the whole population of these sections.

4. Many adjustments were required, especially in estimating the number under (*b*), and while some of the most important ones have been made in the investigation others have had to be disregarded owing to the lack of data—for example, the incidence of severe deafness in persons in State mental institutions.

5. The estimate shows that about one in every six persons in England and Wales is defective in hearing in one or both ears.

6. The number of persons who would be covered by a Deaf Persons Act and partake of its privileges would probably be in the neighbourhood of 150,000.

SOCIAL BACKGROUND OF ILL-HEALTH

The transition from alleviative charity to constructive public service and an active participation in preventive medicine has been manifested in our hospital system by the growth of social service departments. Disease, which used to be regarded as an entity, is now looked upon as an event in a chain of circumstances and restoration to health as a pilgrimage in the reverse direction. Medicine and surgery can be very helpless unless some organization is available to deal with the "social" components in this chain. Defining "social" as that which concerns human associations and the stresses and strains of those associations, Thornton and Knauth[1] have recently presented us with a very clear picture of what this process means in the lives and clinical histories of one hundred consecutive admissions to the Presbyterian Hospital in New York. They show that hospital social service is not merely confined to making prescribed treatment economically possible for the patient, but that in a far wider sense social investigation is implicit in treatment and often invaluable in diagnosis.

The social problems that face the United States and Great Britain are in some respects very different. The absence of national health insurance and the difficulties of full racial assimilation complicate the American picture. The similarities are, however, highly significant and demand close attention in any society which is becoming more and more mechanized and urbanized. A rural community may lack the equipment and specialization possessed by urban dwellers not only for treatment when ill but for the ordinary processes of living. On the other hand, as Thornton and Knauth point out, the town dweller is more migrant and his contacts are more impersonal, so that when he begins to ail he often lacks the individual care and attention of friends or relatives. This was notably so in a majority of the cases in the series, and was a major factor in many in allowing a really serious situation to develop. The population of the United States, tending to be more migrant than ours, showed this to a greater extent than would be evident here, but it is not a factor to be overlooked when considering the redistribution of population. Arising out of this there is a corollary. People need a family doctor in the background. He it is who can see things in their totality and observe the effects of economic, domestic, and other influences before trouble goes too far. Highly organized and specialized hospital and clinic services are necessary, and we need the new industrial clinics that are arising, but the general practitioner is, and must always remain, the backbone of medicine. He must be able to use the hospital and other social service facilities when he requires them, but, conversely, without his aid these services would largely fail to achieve that personal contact between medicine and the patient which is essential not only for effective therapy but for education and prophylaxis.

Apart from this lack of personal service, which affected 65 per cent. of the cases under review, the next most potent social components in illness were faulty personal habits, undue struggles for existence, and dissatisfaction with work. Faulty personal habits can only be corrected by a process of education applied either *ad hoc* to specific cases or as a preventive measure in schools. It is not enough merely to teach hygiene. In secondary schools and universities we need to aim at the inculcation of some sort of biological awareness. That those who administer our complex society can achieve positions of great power and influence without even a nodding acquaintance with the nature of vital processes is a grave error, for it hampers the necessary correlation of historical and economic events with physiological and emotional needs. Such an ordered background would in time affect the general level of thought and would powerfully influence public and private action. In this way the needs of society would be met not only by the provision of material comfort but by the development of satisfactions which would remove some of the main causes of emotional unrest. Dissatisfaction with work is not just being discontented. It means the lack of emotionally satisfying yields from the output of energy. We have to consider this carefully in relation to modern employment, and it is perhaps here as much as in anything that industrial medicine has its new advances to make.

Medicine cannot bring about direct alterations in the economic fabric nor in the work men and women do, but it can influence changes in the methods of doing that work, in the systems of control, and in the various schemes of incentives. To do this it must press for a wider recognition of the clinical effects of good and bad labour management, and it must emphasize the need for a sound biological outlook in social and industrial administration. Whether preventive or curative the social component in medical care is primarily

[1] *The Social Component in Medical Care.* By Janet Thornton, in collaboration with Marjorie Strauss Knauth. London: H. Milford, Oxford University Press. (15s.)

ucational. We have a great task to correlate
: physical and mental welfare of mankind with
:ial states, and this must be done without making
ople soft and introspective. A world full of
ichinery needs a high degree of reason to keep
safe and sane, but the force of emotion remains
strong as ever, full of potentialities for creation
destruction, for increasing health or producing
d aggravating illness.

Miss Thornton and Dr. Knauth have not de-
ibed anything new. They do not claim to have
ne so, but they depict most forcibly a mass of
manity, much of it not uneducated in the
:epted sense, struggling with appalling ignorance
biological and social forces against a stream
competitive economic individualism which
her wears them down so that they become ill,
ysically and mentally, in a vicious circle, or
ich, once they are ill, draws them into the
rtex. In spite of our makeshift ways, or per-
ps because of them, we have in this country
:aped so far from much of the worst effects of
gh-pressure living, but the future is uncertain,
d we must see to it that in attacking social ills
d in evolving new systems we neither leave men
d women at the mercy of forces too great for
:m to stem nor at the same time destroy that
rsonal responsibility and independence which is
:ential for health and happiness. It is a problem
ich must not intimidate us, or assuredly it will
stroy our society.

MESODERMAL SYNDROMES

ke most syndromes the triad of hereditary brittle-
ss of bones, blue sclerotics, and otosclerosis came
be recognized in a piecemeal manner. As early
1788 Eckman established the hereditary nature
one form of fragility of bone in reporting the
currence of fractures in three generations. When
:ording other cases of that nature Spurway, in
: *British Medical Journal* in 1896, remarked on
e blueness of sclerotics in some of his own cases.
iat this was no accidental association was clearly
oved by Eddowes in 1900, also in these columns.
ie further association of deafness occurring in
ch patients in the third and fourth decades of life
is established in 1917 independently by Bronson,
id by van de Hoeve and de Kleijn. The careful
ady by Julia Bell in 1928 in *The Treasury of*
uman Inheritance clearly demonstrated the domi-
int nature of this affection. As with all syn-
omes, it is the exception rather than the rule to
id all the components in one and the same patient,
id in the diagnosis of an individual case the family
history is frequently of paramount importance.
That the disturbance is indeed widespread is brought out by the fact that many of the patients are undersized, quite apart from any stunting of stature due to multiple fractures. Skull deformities were noted by Apert, Bach, and Odinet in 1928, while phlebosclerosis has been reported by Joachim and Wasch. Radiography shows the bone to have a decreased density and the cortex to be thin; excessive calcification is, however, occasionally present in the petrous bone. While fractures may occur throughout life they are less frequent after puberty. Healing is invariably good.

It is still undecided whether the bluish appearance of the sclera is due to thinness of the tissue *or to an increased translucency from diminished calcium content*. Both these views are being supported by both positive and negative evidence.[1] In a general way it may be said that the syndrome is mesodermal in origin, and is thus linked up with the various other mesodermal syndromes, such as arachnodactyly and the more recently described status dysraphicus. Status dysraphicus is not by any means a clearly established entity. It is based on the old conception of Henneberg that faulty closure of the neural tube is the cause of syringomyelia. This conception was worked out in detail by Bremer,[2] who searched in patients with syringomyelia and in their families for developmental anomalies which would seem to result from a spinal dysraphy. He found a considerable number: preponderance of the extended arms over the body length, funnel chest, acrocyanosis, moist, cold hands, kyphoscoliosis, winged scapulae, webbed fingers, inequality of the mammae, spina bifida, anomalies of the ears, highly arched palate, and other signs usually labelled stigmata of degeneration. The work of Bremer widened the conception of syringomyelia, making it part of a well-defined syndrome, hereditary in character, and showing a range from the normal to the definitely pronounced case of syringomyelia. Believing the anomalies to be due to malformation of the spinal raphe, he suggested the name of status dysraphicus. Ocular aspects of this syndrome were elaborated by Passow[3] in papers published during the last few years. He stressed the frequent occurrence of the Horner syndrome and heterochromia iridis, and advanced experimental evidence to show that the faulty embryology in status dysraphicus involved the motor fibres and cervical sympathetic and thus led to the Horner syndrome. The many points that arachnodactyly has in common with status dysraphicus found an

apparent contradiction in the dissimilarity of the ocular complications. Since pupil changes are not infrequent in arachnodactyly, there are points of contact between the two syndromes as well as the dissimilarities, and Passow has tried to explain the ocular complications of both syndromes by a common embryological fault. From a review of the literature on arachnodactyly Pino, Cooper, and van Wien[1] argue that evidence of status dysraphicus is indeed to be found in some of the reported cases of arachnodactyly, and in one case the Horner syndrome seems to have been present.

So little, however, has as yet been reported on status dysraphicus that it is difficult to reach final conclusions. What is interesting is not only the slow recognition of new syndromes but the suggestion that these syndromes have common underlying factors. For the present the building-stones rather than the ultimate edifice are being dimly realized.

THE SPHINCTER OF ODDI

Some people are still sceptical about the existence of the sphincter of Oddi, and E. A. Boyden[2] now suggests that there are two reasons for this. First, it is difficult to separate the action of the sphincter from that of the duodenal muscle which surrounds it, and, secondly, because of the small size, position, and complexity of the sphincter it has been equally hard to demonstrate its independence histologically. Boyden has therefore made a comparative study of the sphincter, and finds that the termination of the common bile duct varies a good deal both in man and in animals. There is no ampulla in the dog, and even in its embryo the bile and pancreatic ducts have separate openings into the duodenum. In some animals the musculus proprius of the common duct is easily separable from that of the duodenum, and in others there is an intimate blending of bile duct and intestinal musculature. The musculus proprius is well seen in the opossum, in which the ampulla of Vater and its duct are clothed with a thick double layer of smooth muscle consisting of circular and longitudinal coats. In man the muscle of the ampulla is a relatively weak layer consisting of longitudinal fibres overlying an inner circular layer, but proximal to this there is a zone of more powerful circular fibres surrounding the bile duct. These may be designated the sphincter choledochus, and there is evidence that these fibres can hold up the column of bile in the duct so that pancreatic juice alone may under certain conditions enter the duodenum. Magnesium sulphate introduced into the duodenum relaxes the sphincter choledochus and allows an admixture of bile with pancreatic juice. Boyden's studies show conclusively that in the opossum, guinea-pig, dog, and man the pars intestinalis of the bile channel and its associated duct of Wirsung (if this be present) are ensheathed in a two-layer musculus proprius which may legitimately be designated the sphincter of Oddi. In the *Journal* of December 12 last year (p. 1203) we drew attention to some valuable clinical research at the Mayo Clinic by Butsch, McGowan, and Waltman Walters on the action of certain drugs on the emptying mechanism of the common duct. One of the most important results of this research was to show that morphine, even in small doses, caused an increase of intrabiliary pressure, and it was concluded that this drug should be avoided after operations on the biliary duct. Some further experimental work on the resistance of the sphincter in man has been reported lately from New York.[3] Observations on the resistance of the sphincter were made with apparatus rather like that used by the workers at the Mayo Clinic. The patients in whose common ducts T-tubes had been placed had all had operations on the biliary tract, so that only pathological conditions were available for study; we must therefore be chary of applying conclusions drawn from them to normal conditions. From their investigations, however, and particularly from those made on cases in which infection was minimal and conditions approached the normal, the authors conclude that the resistance of the sphincter of Oddi is normally somewhere about 150 mm. of water. Doubilet and Colp find also that their experimental work supports the contention that magnesium sulphate is much more effective than ordinary or even fatty meals in causing relaxation of the sphincter. They also confirm what Oddi first observed—that spasm of the sphincter is produced by the local application of hydrochloric acid. Their experiments support the conclusion of the workers in the Mayo Clinic that morphine causes severe spasm of the sphincter. In certain cases this spasm lasted over three hours and was not abolished by atropine. They state that a satisfactory drug for the treatment of biliary colic is still to be found.

ANTI-PLAGUE VACCINE—LIVE OR DEAD?

Plague continues to exact a heavy toll in many different parts of the world. Whenever possible the most satisfactory way to combat it is to direct a fierce attack upon the rat population, for, as the English Plague Commission demonstrated, the continuance of the disease in man depends upon infection of these rodents. By constructing rat-proof houses for the native population long-standing foci of disease may be eliminated. For example, at Malang, in East Java, where plague claimed 22,000 victims between 1911 and 1915, the disease has been completely stamped out by rebuilding 140,000 houses for the natives. Not a single indigenous case, in fact, has occurred since 1916. Such radical treatment, however, is not always possible. Where rats cannot be built out of existence measures must be taken to raise the resistance of those who are likely to be exposed to infection. For this purpose vaccination is now being extensively used. The type of vaccine varies. In India Haffkine's dead vaccine is still favoured; in the Dutch East Indies a living avirulent vaccine is preferred. It is difficult on the available evidence to decide which of these two vaccines is the more valuable. Sokhey and

[3] Doubilet, H., and Colp, R.: *Surg. Gynec. Obstet.*, March, 1937, p. 622.

Maurice[1] at the Haffkine Institute, Bombay, have been devoting themselves in recent years to improvements in the preparation and standardization of the dead vaccine. They find that cultures of the plague bacillus can be kept fully virulent if stored at 4° C., but gradually become avirulent if weekly subcultures are made and kept continuously in the incubator. For the preparation of their vaccine they insist on the use of a fully virulent strain. Killing the organisms by heat at 60°–70° C. for one to two hours, as has been done in the past, partly destroys their antigenic activity. If, on the other hand, they are exposed to a temperature of 55° C. for only fifteen minutes their antigenic activity appears to remain intact. Standardization of the vaccine is carried out on white mice. These animals are very susceptible to experimental inoculation, and almost always die after a subcutaneous injection of about fifty living bacilli. The protective action of any given vaccine can therefore be assessed on a more or less quantitative basis. Comparison between a heat-killed vaccine made from a virulent strain and a living vaccine made from an avirulent strain seemed to show that the former was considerably more effective than the latter in protecting mice against infection. From the Dutch East Indies, on the other hand, come very promising reports of the use of an avirulent living vaccine. In a communication made to the International Office of Public Hygiene Vogel[2] summarizes the results obtained by Dr. Otten, who is director of the Pasteur Institute at Bandoeng. In the two districts of Bandjaran and Batoedjadjar 37,435 subjects were vaccinated and 39,483 were left as controls. In the first group the death rate from bubonic plague was 1.01 per 1,000, in the second group 5.05 per 1,000. These results, favourable to vaccination as they were, might have been even more so if the less susceptible infants and young children had not mainly been included in the control group. It may be noted that the incidence of pneumonic plague was not greatly dissimilar in the two groups, there being a total of thirty-six cases in the vaccinated and forty-eight in the control group. The virulence of this infection, however, is such that nothing but a high degree of immunity can be expected to protect against it. On the whole the results obtained appear to have been very satisfactory. Most suggestive is the favourable impression among the natives themselves; as many as 90 per cent. are now coming forward for vaccination. It will be interesting to hear the results of a similar field trial made with the newly standardized Haffkine's vaccine.

IDENTIFICATION BY THE RETINAL PATTERN

Any method of identification has great legal value. The principal methods at present in use are, of course, the classification of finger-prints and of dentitions, but Dr. Carleton Simon, criminologist of the International Association of Chiefs of Police, has developed a method of identification by means of the blood-vessel patterns in the retina. Dr. Leo Haber[3] suggested in 1921 that retinal photographs might be used for identification, as the vascular pattern was unchangeable through life and the only difficulty lay in classification. In 1935 Dr. Simon[4] described, with Dr. I. Goldstein, a method of classification based on a retinal protractor, with the optic nerve as its centre. He uses only the vein pattern, because the arteries, having a lighter colour, are not definite enough. The zero axis is a line drawn from the centre of the papilla to a point 10 mm. distant on the superior temporal vein, and the notation describes the angles at which veins or branches intersect two circles, one of 10 mm. and the other of 5 mm. radius. His system, which has been gradually simplified in use, needs a minimum of figures and can, he says, be mastered in a couple of hours. His claim that it is a valuable adjunct to finger-print identification in certain cases appears to be sound, but its practical value, as Dr. Simon himself points out in a more recent article,[5] must be proved by time.

AN INSURED PROFESSION

Another year of progress—the thirtieth in its history—has been recorded by the Medical Insurance Agency. The figures presented to its recent annual meeting showed a new record in every particular. The gross income of the Agency is up by some £900 on the year before, the rebates to members are up by some £400, and the grants to medical charities by over £500. The premium income on policies effected in 1936 was £280,000, and the life assurances completed represented £486,000, in each case a fourfold increase on what they were ten or twelve years ago. But the full story of an excellent piece of work for the profession is not told by these or any figures. The Agency has established itself as a disinterested body, not out for profit-making but able to offer to the profession impartial and expert advice on all matters of insurance. Insurance is nowadays a matter for experts, and there are special circumstances connected with medical practice which make expert advice on this subject more than ordinarily desirable. The Agency has set itself with great success to give advice to medical men and women on their insurance contracts, and by a system of rebates on practically all classes of policies to effect a direct saving for members of the profession on the amount paid in premiums. It is not in itself an insurance company, and very much of the business that it carries through is reflected in the profits of other concerns, but it has the satisfaction of performing a real service. At the annual meeting it was stated that owing directly to the action of the Agency there is now, in the shape of policies held by members of the profession in life, endowment, and other forms of insurance, a capital value of four and a half million pounds sterling. This represents not only an individual security for the holders of the policies and their families but also in a sense a collective security for the profession, because the effect will be eventually to reduce the number of claims upon medical charities. Many of the cases which are now helped by the Royal Medical Benevolent Fund or Epsom College would never have arisen if the claimant had effected suitable

insurances. While on the one hand the Agency is thus diminishing the need for medical charity at some future period—though the existing need requires no emphasis—it is also making grants to such charities, apparently as a reparation for not having been in existence at an earlier period. During the thirty years of its existence medical charities have benefited from its operations to the extent of £42,700. At the recent meeting, from the surplus income available, a distribution was made of £2,830 to the Royal Medical Benevolent Fund, £730 to Epsom College, and £400 to the Sir Charles Hastings Fund. Some particulars were also given of the volume of business transacted during 1936. In life and similar assurance 428 proposals, representing a capital sum of over half a million, were received and 367 of them completed. Additional motor-car insurances to the number of 332 were effected. Increases were reported in accident and sickness insurance and employer's liability and household insurance. On the basis of these figures the medical profession, commonly supposed to be unbusinesslike, is growing visibly in prudence. It is noted that the tendency is always in the direction away from special forms of insurance and towards comprehensive policies, and that no doubt is to the good. Schemes for pension benefit and for loans for purchase of house or practice continue to be popular. The committee of management, of which Sir Humphry Rolleston is chairman, with fourteen other medical members, is to be congratulated on the continuing progress of the Agency in all its undertakings.

THE HOSPITAL OF TO-MORROW

Many of the older hospitals can hardly be said to have any architecture. They are amorphous growths, and their piecemeal extension has prevented the efficient planning of wards and departments and services. An enlightened architectural intelligence, however, is now at work in hospital construction, and although no one can predict what future developments may render even the most modern constructions out of date, some of the most recent work is not only a delight to the eye but furnishes an example of perfect adaptation to modern ideas in institutional treatment of the sick. Some of these are illustrated in a special hospital issue of the *Architects' Journal* (June 24, 1s.). The views include the Birmingham Hospital Centre, which when completed will accommodate over 800 patients, with a modern teaching hospital and medical school; the Harefield sanatorium for the Middlesex County Council, with wards that give the greatest possible exposure to sunlight, while privacy is obtained by means of small ward units; Scarborough general hospital; the infectious diseases hospital at Paisley, and the Welwyn Cottage Hospital; also a number of outstanding works in London, the nurses' house of the Hospital for Sick Children, which received an award of the Royal Institute of British Architects for exceptional merit; the extensions of St. Bartholomew's; the new Westminster Hospital rising at Millbank; and that very dignified and beautiful structure, the Royal Masonic Hospital at Hammersmith. Something is also shown of continental developments; for example, the remarkable arrangement of stepped sun balconies and clerestory windows of a sanatorium in Poland. The largest problem in hospital construction is vertical versus horizontal planning. The vertical hospital has great advantages to offer in convenience for the staff, but it is also very costly and, unlike the horizontal hospital, not easily altered when it becomes out of date, as it may easily do in twenty years. One of the specialist writers in the *Architects' Journal* suggests that during the next ten years hospital designers will be most concerned with the provision of special hospitals in which planning and equipment will probably show more rapid advances than construction—particularly the equipment and arrangement of free circulation within the special departments. One important point is the elimination of noise. Some hospitals cannot be built beyond earshot of busy main roads. A good deal of noise can be avoided by double windows, but then ventilation becomes a special problem. Moreover, when outside noise is stopped inside noises remain and may seem to be intensified. Rubber floors, doors with effective silencers, the replacement of bells by coloured lights, and the use of acoustic materials go some way to diminishing the problem. Another detail is the operating theatre. The theatre unit itself has reached a high degree of development and has become more or less standardized, but the difficulty remains in a teaching school of any size of providing accommodation for students within the theatre. It is suggested that the eventual solution of this problem lies in the provision of an optical arrangement whereby a view of the operation may be projected on to a screen in an adjoining room.

NATIONAL RADIUM TRUST

The National Radium Trust met on June 28 at the Privy Council Office under the chairmanship of Viscount Halifax, Lord President of the Council. Plans were reviewed for making available a further substantial amount of radium. The Earl of Donoughmore was reappointed for a further period chairman of the Radium Commission, which allocates the Trust's radium and supervises it in use. The Trust welcomes gifts and bequests of all kinds in furtherance of its objects, including trusts subject to special conditions; it is expressly authorized to accept them under the Royal Charter granted in 1929. Of the Trust's funds £150,000 was contributed by public subscription in that year as a thankoffering for recovery of King George V. Mr. R. Stanton has been appointed secretary of the Trust in place of Mr. George North, resigned.

By an Order of the Committee of Privy Council Mr. W. M. Goodenough is appointed a member of the Medical Research Council on the retirement of Lord Mildmay of Flete. Mr. Goodenough also succeeds Lord Mildmay as Treasurer of the Council.

The Scottish Association for the Deaf has published a leaflet entitled "Advice to Parents of Young Children," which draws attention to the importance of the early detection of deafness. The leaflet can be obtained on application to the hon. secretary's office, 3, Midlothian Drive, Waverley Park, Glasgow, S.1.

THE DOCTOR IN POLITICS AND DIPLOMACY

SIR ARTHUR MACNALTY'S LECTURE

The Sir John MacAlister Memorial Lecture was delivered at the London Temperance Hospital on June 24 by Sir Arthur MacNalty, Chief Medical Officer of the Ministry of Health, who surveyed the whole of history, ancient and modern, in describing outstanding examples of "The Doctor in Politics and Diplomacy."

There was hardly a field of high endeavour, said the lecturer, in which men with medical qualifications were not to be discovered. Two men eminent in medical science had contributed also largely to laying the foundations of the science of politics. One of these was Aristotle, tutor and adviser of Alexander the Great, who was an anatomist before he became a politician. The other was Sir William Petty (1623–87), founder of the science of political economy, a graduate of medicine at Oxford, later physician to the Army in Ireland, who relinquished medicine and devoted the rest of his life to political science.

Medical Victims of Politics

When the doctor turned from healing to politics too often he embarked upon an uncharted sea of peril. In mediaeval times the physician's knowledge of drugs was liable to be invoked by unscrupulous politicians to remove their rivals. Catherine de Medici employed an Italian physician named Cosmo Ruggieri, who was supposed to have poisoned her sons at her request; probably this was untrue, but Ruggieri appeared as a sinister character in Harrison Ainsworth's *Crichton* and Balzac's *Sur Catherine de Medici*. The Earl of Leicester had an Italian physician, Julio, who was affirmed to be a skilful compounder of poisons. Another of Leicester's physicians, Walter Bayley, was also said to have a skilled knowledge of poisons which he placed at the disposal of his patron, but this must be doubted in view of Bayley's honourable conduct in the case of Amy Robsart and his life of professional integrity. Less fortunate than Bayley in the web of Elizabethan politics was Roderigo Lopus or Lopez, the Jewish physician of the queen and physician to St. Bartholomew's; he was hanged for high treason. Sir George Wakeman, physician to Catherine of Braganza, who had "the best reputation of any Roman Catholic physician in England," was denounced by Titus Oates in the days of the Popish plot, but his acquittal dealt a blow at the plot and freed the queen from suspicion. One of the most unfortunate of medical plotters was the humane and gentle Archibald Cameron (1707–53), who took medical charge of the forces raised by his brother for the Young Pretender. Although he never bore arms he was attainted for high treason and executed at Tyburn.

Two Doctors of the "Terror"

Sir Arthur MacNalty next mentioned two doctors of the "Terror." One was Dr. Guillotin, doctor of medicine of Rheims University and one of the founders of the Académie de Medécin, whose professional fame, however, was eclipsed by his association with the deadly instrument which bore his name, but of which he was neither the inventor nor the victim. In the Constituent Assembly he proposed decapitation by machine as the most humane method of execution. He had no share in the excesses of the French Revolution, at which his humane spirit must have shuddered. The other was Marat, at one time a practitioner in Soho and an M.D. of St. Andrews. When the tide of revolution rose in Paris Marat abandoned medicine for politics, and the rest of his life was closely interwoven with public events. He remained independent, criticizing in turn every party in power. After his assassination he was accorded a magnificent funeral in the Pantheon, but then came reaction; the patriots rose against his memory and flung his ashes down a sewer in the Rue Montmartre. Had he adhered to his profession he would have gone down into history as a great scientific physician.

The Doctor as Ambassador

The lecturer next discussed the doctor as ambassador. Several rulers of Russia had from time to time the services of English physicians, who acted also as unofficial envoys of the Government. One of these was Thomas Dimsdale, who went to St. Petersburg in 1768 at the request of the Empress Catherine. His successful inoculation of the Empress and her son against smallpox resulted in the granting to him of the rank of baron of the Empire, counsellor of State, and the post of physician to the Empress, with, incidentally, a pension and a handsome present.

The first medical ambassador appeared to have been Sir Thomas Elyot (1490–1546), who was ambassador to the court of the Emperor Charles V. In the seventeenth century an anatomist, John Finch, became Turkish Ambassador. Another highly distinguished medical ambassador was Sir Charles Richard Vaughan (1774–1849), Radclyffe Training Fellow in the University of Oxford, who during the Peninsular War was secretary of the Legation at Madrid and acted for a time as British Minister there. Afterwards he was Minister Plenipotentiary to Switzerland and Envoy Extraordinary and Minister Plenipotentiary to the United States. Medicine had a second ambassador to the United States in Sir Auckland Geddes in 1920.

Medical Powers Behind the Throne

Among the friends of British monarchs were two physicians, upright, selfless, and able. One was Sir William Knighton, private secretary and privy purse to George IV. Knighton was an M.D. of St. Andrews, Aberdeen, Lambeth, and Göttingen, and practised in Hanover Square, chiefly as an accoucheur. He was appointed by the Prince Regent to an important office in the Duchy of Cornwall, and was frequently employed by the Prince when he became King on confidential missions abroad. He attended the King night and day in his last illness. The other was Baron Stockmar, adviser to the young Queen Victoria. Stockmar had been an Army surgeon and personal physician to Leopold of Belgium. The advice he gave to the Queen appeared always to be frank, ripe with experience, and dictated by the highest motives. Palmerston called him the most disinterested man he had ever met. His political knowledge was immense, his influence in high affairs unbounded. Like his medical work his statecraft was based on high principles and made for good.

Medical Prime Ministers

Medical prime ministers had presided over the destinies of Denmark, France, Canada, and South Africa. The Danish prime minister was Struensee (1737–72), who became virtually dictator of Denmark in 1770, but he ended his career on the scaffold. The French prime minister was Clemenceau (1841–1929), whose forbears for 300 years were doctors. Hardly had he begun to practise in Montmartre when politics claimed him. "The Tiger" made and destroyed ministries at his pleasure, but his political integrity was never doubted. The last phase of his career, when he led the last War Government of France, was still in the public memory. Sir Charles Tupper, a doctor, for a time guided the destinies of Canada with wisdom and success; he did much to bring about the federation of the Canadian provinces. The most romantic of medical prime ministers was Leander Starr Jameson, prime minister at Cape Colony from 1904 to 1908. He was born in Edinburgh, and studied medicine at University College Hospital, London,

went to South Africa on grounds of health, and began practice at Kimberley in 1878. The lecturer recalled the circumstances of the Jameson Raid. Mr. Huggins, the present Prime Minister of Southern Rhodesia, was a Fellow of the Royal College of Surgeons.

Sun Yat Sen (1867–1925), who overthrew the Manchu regime and rose to be the "father of the Chinese republic," was also a doctor. One of his tutors and friends in Hong Kong was Sir James Cantlie.

Medical Training as a School for Statecraft

From this study of the doctor in politics and diplomacy, Sir Arthur MacNalty concluded, it would be readily apparent that members of the medical profession had played no small part in administration and government, and that they owed their success in a measure to their previous medical training. Not a few could attribute their rise directly to the recognition in their professional capacity of their fine qualities of character. This was certainly true of Sir William Petty, Sir John Finch, Sir William Knighton, Baron Stockmar, and Sir Starr Jameson. The medical eminence previously achieved by Guillotin, Marat, and Struensee certainly paved the way to political influence. Clemenceau rose to power through his gifts of oratory and literary expression rather than his knowledge of medicine. For the most part these men carried into politics the high ideals of the Hippocratic calling. The majority had not only been great but good men. Even in the exceptions to the rule redeeming qualities could be found. Marat had high political aims, though his methods of securing them were monstrous and indefensible. Struensee was a libertine and something of a scoundrel, yet he honestly desired to better the condition of Denmark.

"To-day in this country the doctor is playing an important and progressive part in the national life. He need not necessarily go into politics to do this, because the politicians come to him for advice and counsel. A special kind of medical adviser has arrived, the medical officer of health, who guards the health of the persons in his area and advises his council on appropriate measures for securing it. The leaders of the medical profession are frequently consulted on desirable health reforms. The Health Committee of the League of Nations has done much to improve health conditions abroad and to make medical knowledge and experience international. In all these ways the doctor exercises an influence on political thought and legislative action."

Sir Arthur MacNalty said in conclusion that from all this it was evident that the professional advice of the doctor was often utilized by the State not only for the benefit of individual patients but for the betterment of the whole community. His role was generally a more sheltered and inconspicuous one than that of the medical politician. Still, when the physician laid aside the rod of Aesculapius to enter the dust of the political arena his previous medical training stood him in good stead, and he might rise to be the chief executive of his country or to be its representative in another.

L. Bayer (*Zbl. inn. Med.*, May 1, 1937, p. 369) discusses at length the two apparently opposite theories of the nature of the inflammatory reaction—namely, the theories of Spiess and of Bier. Spiess introduced the conception of the cure of inflammation by anaesthesia, while Bier has shown the importance of hyperaemia for the healing of inflammatory conditions. The author was able to prove by experiment that a complete anaesthesia inhibits the setting in of an inflammation following injury, and that it favours healing when applied after the inflammation has already set in. The anaesthesia seems to act very favourably on chronic as well as on specific inflammatory changes —for example, lupus. The same principle applies to the cure of gastric ulcer. Acute and chronic ulcers heal rapidly and surely following repeated applications of an anaesthetic to the ulcer.

INCIDENCE OF WAR NEUROSIS

The third annual conference called by the Ex-Services Welfare Society was held in London on June 25 under the chairmanship of Dr. EDWARD MAPOTHER, when the subject taken for discussion was the control of the incidence of war neurosis.

The CHAIRMAN, in an opening address, said that it had been stated that cases of war neurosis formed only 2 per cent. of the medical casualties of the last war, but in reality if all that was truly neurotic had been called by that name the figure would have been much larger. One medical officer who had acted as a medical specialist in a hospital at home during the war estimated that one-third of the admissions to his wards were for purely neurotic complaints. In the next war disability through terror rather than through physical injury was likely to play an even larger part. One reason for this was the increasing importance of gas warfare; everyone agreed as to the frequency with which neurosis followed the experience of a gas attack. Three groups of problems arose under this subject: (1) the treatment of the malingerer before and after enlistment; (2) elimination of the potential neurasthenic during training; and (3) prevention and treatment of war neurosis actually in the field.

Malingering

The first of these problems raised questions of vital importance with regard to the examination of the recruit. It might be assumed that almost immediately after the outbreak of the next war the principle of universal liability to service would be accepted, subject to some form of exemption for real conscientious objectors. In 1914 the sudden expansion of the Army made complete chaos of the arrangements for the examination of recruits; in some cases a medical man examined 400 potential recruits a day. On a future occasion it would probably be possible to make better arrangements. It might well be questioned whether any definite exemption from liability to service should be granted on the evidence of medical certificates unless these were furnished by a doctor who had had the man under observation for the disability in question during several years. If examination of recruits was proceeding at a reasonable rate it might be possible to provide places of observation for doubtful cases.

As for the distinction between malingering and hysteria, objective evidence could be only indirect. The diagnosis must be based upon such things as variation of symptoms when the man was unaware of observation, variation according to his interests from time to time, discrepancies between his subjective symptoms and his behaviour, and, of course, his general character and his attitude towards treatment and recovery. In the pre-enlistment cases diagnosis might be more easy because the condition was less likely to be associated with anxiety neurosis. Malingering was often superimposed on genuine anxiety neurosis in the case of a man who had actually been in the line.

Elimination of the Neurasthenic

With regard to the second problem, the elimination of the potential neurasthenic, Dr. Mapother continued, it would be impossible to expect a medical man making a preliminary examination of recruits to give an exact forecast as to liability to neurosis. He might be able, however, to refer such cases to an expert who could judge whether the attention of the medical officer of the unit should be specially directed to him, and whether the man should be sent to an observation centre. There had recently been an active search for definite psychological tests of temperament, and there was evidence that these had some value in enabling a forecast to be made of probable response in future situations. It was so important to keep fighting units free from people who by their neurosis would destroy the morale of the unit and fill

the hospitals that it would be advisable to carry on some intensive research work into the possibility of identifying the men likely to break down.

The best way of eliminating the potential neurasthenic was to train him into a good soldier, and that was the task of the combatant officer. The men should be told during training that everyone was apt to be frightened, that it was neither a discredit nor an excuse for shirking duty, and that the interest of the individual soldier had to give way to the interest of the nation. It might be useful for combatant officers to note in their men any undue disturbance during firing practice, when learning to ride, or on first entering a gas chamber, and to refer those showing such disturbance to the medical officer of the unit.

It was recognized that the freedom of a divisional unit from war neurosis mainly depended upon the personality of its medical officer, upon his knowledge of men, and his handling of them. A very distinguished neurologist had said that the regimental medical officer should not be a peace-time psychologist, and with that he agreed, but personal experience suggested to him that there was room for one well-trained psychiatrist in a division, available for consultation with the medical officer of the unit, and also available to the A.D.M.S. when a high incidence of neurosis began to appear in a particular unit.

War Neurosis in the Field

The prevention in a collective sense of war neurosis among troops in the field, said Dr. Mapother, was a problem identical with that of the maintenance of morale, and was therefore largely one for the combatant officer. It depended upon such factors as contentment, the team spirit, and belief in the cause for which the men were fighting. It was generally felt by combatant officers that even if war neurosis was not regarded as discreditable to the individual an epidemic of it was discreditable to the unit in which it occurred. The introduction of the term "shell shock" to include emotional disturbances had been a serious mistake. He thought it was also generally agreed that, so far as military exigencies allowed, very few functional cases should have been sent back to England. It might have been necessary to discriminate between hysteria and anxiety neurosis, and send back men suffering from the latter condition, but even they should have been sent to hospitals where strict discipline was maintained. Many of those with most experience held that there should be no discharge from the Army during war-time on account of functional disturbances.

Dr. C. S. MYERS, referring to the treatment of war neurosis in the field, stressed the importance of a man being seen by a specialist immediately he was sent away from the fighting line. There should be specialists at the clearing stations to differentiate between cases which would be curable in two or three weeks and the severe cases which required evacuation to the base hospital, where again there should be a specialist to decide whether the cases should be sent to England or not. His own experience had been that where there was dissociation of any kind, either exhibited physically, as in hysterical paralysis, or in loss of memory, immediate treatment was of the utmost importance. There were no certain tests of temperament and character at the present time, and it was very desirable that further research should be carried out on the subject. Major-General H. A. EMERSON (Director of Hygiene, War Office) said that the subject of examining recruits was receiving consideration, and an attempt was being made to evolve a system which would give a reasonable rate of examination. At such an examination men would only be marked unfit if definitely so; those about whom there was any doubt would be marked as temporarily unfit and reserved for observation.

Potential War Neurotics

Dr. W. R. D. FAIRBAIRN (Edinburgh) said that the training period should be used for the elimination of potential as well as overt neurotics, and the situation would be most practicably met by a staff of visiting psychiatrists being allotted to each training area. The elimination of potential war neurotics would be best secured if every recruit received a psychiatric examination, but such an arrangement would be rendered impracticable by the insufficient number of psychiatrists, so it would be necessary to select the recruits for the psychiatric examination. The selection could best be made by the visiting psychiatrist receiving a verbal report on each recruit from those best qualified to observe his daily reactions—that is, his immediate superiors—and also a report on his previous nervous history from his family doctor. From those reports the psychiatrist could select the recruits for personal examination. He thought that psychiatric science had reached a stage at which, given adequate data, the psychiatrist ought to be able to eliminate a fair proportion of potential war neurotics from the main body of recruits during the training period.

Major J. BENNETT said that in his experience deliberately attempted simulation was not common in our present peace-time Army, but malingering by affirmation that a condition still remained which in reality no longer existed was more common. Such cases merged gradually into those which were regarded as neurotic, and no sharp line of demarcation could be drawn. The longer the period spent in hospital the more difficult became the problems with which the medical officer was confronted. Intensive efforts to cut down periods spent in hospital must be an important factor in the control and incidence of war neurosis. He felt strongly that there was a risk of increasing the incidence of hysterical mental states in too often acknowledging defeat by classifying such cases as unfit for service. Mental defects associated with hysterical modes of reaction called for invaliding, but other cases required individual consideration.

Effective Service of Neurasthenics

Dr. J. F. E. PRIDEAUX (Ministry of Pensions) said that he had thought it would be interesting to ascertain the effective service of the neurasthenic. He took for comparison the healthy soldier who had been only slightly wounded in the arm or leg. The effective home service of the slightly wounded, healthy soldier was 33.2 months and that of the neurasthenic 32.8 months. With regard to oversea service, the effective service of the slightly wounded, healthy soldier was 17.8 months and that of the neurasthenic 19.6 months. Some neurasthenics did very good service over-seas for four years, while others did only a month or two, and it would be an advantage if that type could be eliminated. He suggested that there should be a closer examination of the trainee, that reports should be made by N.C.O.'s and company officers of any special stress shown during gas practice, gunfire practice, and so on, and also that there should be a longer period of training in any doubtful cases. It had struck him that the greater number of cases had broken down under the age of 20 and over the age of 35, and it would therefore seem that those under 20 should have a longer period of training and those over 35 more frequent periods of rest behind the front line. There was no reason why a more careful examination of the officers should not be carried out, every officer being examined by a neuro-psychiatrist. Instruction with regard to neurasthenia should be given to medical officers, and there should be some improvement in the education of medical students in that respect.

Dr. BERNARD MYERS urged that in doubtful cases in the examination of recruits a further investigation should be made and reports obtained from the school master, the employer, and the family doctor. It was found in the New Zealand Forces during the war that if a man who had broken down could be got back to the line quickly he was usually fit for active service again, but if he got right away and associated with other neurotics his condition became hopeless. Dr. H. B. JEFFS (Department of Pensions and National Health, Canada) said that a

considerable amount of wastage in the Canadian unit during the war was avoided by the establishment of a rest station behind the lines to which men slightly shell-shocked or slightly neurasthenic were sent.

German Experience

Dr. MAYER GROSS (Maudsley Hospital) said that in the German Army during the war there was an increasing amount of war neurosis. At the beginning there was greater choice of men, and those who were maladjusted from the social point of view could be eliminated. It was a very significant fact that in one of the large hospitals in Germany where neurotics were treated it was found that 50 per cent. of those neurotics were former criminals and had a considerable list of convictions. He was doubtful whether there was in existence at the present time a sure test for morale, or courage, or other qualities which were necessary in war time to avoid neurotic breakdown. The best and most reliable method, he thought, was that used in routine psychiatry—namely, an investigation into the life-history of the patient and the obtaining of records from his school and his employer.

With regard to the question of treatment it was found during the last war that it was most inadvisable to send neurotic cases home. In 1916 of 435 war neurotics who had been sent home to special hospitals and had been cured and discharged only twenty-seven went back to the front line, and of those twenty-seven only five did their full service as privates in the front line; all the others went to ammunition factories and so forth. In view of that an effort was made in the German Army to treat neurotics in the base hospitals instead of sending them home.

Dr. L. H. WOOTTON (St. Ebba's Hospital, lately Ewell Colony) stressed the importance of having consultant psychiatrists in the field. During the war he had been acting as a battalion medical officer, but eventually it was discovered that he knew something about psychiatry, and he was asked to see various people who had been accused of cowardice, sleeping on duty, and so forth. He found that cases of dementia praecox were being treated by field punishment No. 1. Nearly all the cases were genuine ones, and ought to have been treated by an expert; the battalion medical officers had no knowledge at all of how to deal with them. He saw a considerable number of cases during the war of men who had been accused of dereliction of duty in the field, for which they could have been shot, and they were genuine psychotics. With regard to the possible shortage of psychiatrists in the next war, if it was a war of terror against both the military and the civilian population, there might be more cases of war neurosis than of war wounds, and it was most important that there should be an adequate supply of properly trained psychiatrists. Badly applied psychiatry could do quite as much harm as badly applied surgery.

Dr. JAMES MACDONALD (Glasgow) thought it should not be difficult for a man of experience to detect the malingerer; there was nearly always something that did not fit properly into the clinical picture. The real difficulty was in segregating the malingerer from the hysterical patient, but the trained psychiatrist and neurologist ought to be able to distinguish between them. It did not follow that when a psychotic had been detected he should be eliminated from the Army; many psychotics could do useful work in the field. With regard to the detection of potential psychotics psychiatry had not yet reached the stage when the psychiatrist could give a definite opinion even after the most careful examination. Laboratory tests helped a little, but they were not by any means a sufficient and reliable guide; the real test was the practical test, when a man came under the actual strain and stress of war. There was an urgent need for more psychiatrists. He suggested that young men should be persuaded to join the Territorial Army, because the great danger lay in the sudden imposition of war conditions upon men who had never had any idea of going to war.

Value of Physical Training

Colonel J. HEATLY-SPENCER (Consulting Physician to the British Army) thought it was desirable that neurotics should be eliminated from the Army, but the question arose as to where they were to be sent in the next war. There might be just as much danger in the areas behind the lines and at home from air raids as there was in the fighting line. Army training aimed at teaching a man self-reliance and responsibility as well as the handling of weapons. He thought it was successful in that aim, but it took some years to make a good soldier, and the difficulty really arose in the civilian population enlisted at short notice. He suggested that the problem ought to be examined on a wider basis and at an earlier stage than that of actual enlistment. He would take as examples two widely differing types: first those men who flocked to any excitement from this country and all over the Empire. They had developed, mainly from an open-air life, a sense of self-reliance and responsibility, a mental resiliency, and a standard of conduct which placed personal bravery before anything else. Such men did not break down. At the other extreme there were the men taken suddenly away from industrial life in England or elsewhere; many of them had had very little opportunity of developing self-reliance and responsibility which would enable them to deal with the unexpected, or with danger when it suddenly confronted them. He did not think they required military training so much as the opportunity to develop themselves, particularly in the physical sphere, and to establish contacts which would enable them to develop self-reliance. In the youth movement, the playing field movement, and other such movements he thought the ultimate solution of the problem of neurasthenia, not only in the Army but also in industrial life, would be found.

The CHAIRMAN, in summing up the discussion, said he thought everyone was agreed as to the need of treatment from the first moment, and that meant that there must be a large supply of psychiatrists available if the problem was to be dealt with in the field as well as at home

At the luncheon, given by Admiral of the Fleet Sir REGINALD TYRWHITT, which followed the conference, it was announced that the Ex-Services Welfare Society proposed to establish a home on the coast for the use of ex-service men in mental hospitals in Great Britain who, in the opinion of the medical superintendents, would benefit by a change of surroundings.

STUDENTSHIPS AND FELLOWSHIPS IN CLINICAL SCIENCE AND EXPERIMENTAL PATHOLOGY

The Medical Research Council invites applications for a second series of Studentships and Fellowships intended to encourage young British medical graduates of special ability and original mind towards becoming investigators in those branches of medical science which are concerned directly with disease as it occurs in human beings. This field of research includes investigations into disease or manifestations of disease in patients, together with experimental work of an immediately relevant kind.

Post-Graduate Studentships

Six post-graduate studentships are offered for medical graduates who have already held house appointments and are strongly inclined to a career in clinical science or experimental pathology. Each selected student will receive an inclusive grant at the rate of £200 per annum, during a period not exceeding twelve months, for personal maintenance while undertaking approved courses of study in this country such as may be regarded as best calculated to advance the student's training in methods of research. This study may include modern languages and such advanced physiological, pathological, and special clinical work under recognized teachers as

may be regarded as forming a suitable preliminary to serious research work to be undertaken later; but the approved course may not include studies of which the purpose is to enable the student to pass further examinations.

Research Fellowships

The Council also offers four research fellowships for candidates of similar qualifications who have already had some experience in the use of research methods. Each Fellowship will be tenable for one year at the ordinary value of £250 per annum, and will be renewable in approved instances at the rate of £300 per anum for a second year. These Fellowships are intended as probationary appointments for research in clinical science or experimental pathology under suitable direction in this country. Research expenses may be provided in addition to stipend.

Applications should be lodged with the Secretary, Medical Research Council, 38, Old Queen Street, London, S.W.1, before October 1, 1937. Forms for the purpose will be supplied on request.

TUBERCULOSIS IN CYPRUS

We have received from the National Association for the Prevention of Tuberculosis the following report of its mission to Cyprus.

A Request for Help

During the year 1935 two members of the Council of the N.A.P.T., Mrs. Pam and Mr. H. A. Baker, visited Cyprus and had their interest aroused by what they were told of the serious ravages of tuberculosis on the island. It was pointed out to them that Cyprus is a poor island, with much to do with its money upon developing essential services; its governing authorities would welcome help and advice from the N.A.P.T. in dealing with the problem of tuberculosis, which hitherto had not been seriously taken in hand.

The request was favourably received by the Council of the N.A.P.T. with the result that an immediate contribution of £100 towards the Cyprus anti-tuberculosis campaign was followed by the promise to send to Cyprus a medical officer and a nurse with special experience of the work of a tuberculosis administration. The officers selected for this duty were Dr. Noel Bardswell, F.R.C.P., and Nurse Jays of the Seamen's Hospital, Greenwich, who has lived in the Near East for many years and speaks Greek, the chief language in Cyprus. The N.A.P.T. officers took up duty in Cyprus on November 1, 1936, and have since then worked in close co-operation with the Public Health Department of the Cyprus Government. Dr. Bardswell has just arrived home on leave, and is making a report to the N.A.P.T. on the work he has so far carried out on the island.

Local Conditions in Cyprus

Cyprus became a Crown Colony during the great war: Britain then took over the country, which centuries of neglect had left in an undeveloped condition. It is still backward and primitive, and not yet ready for a highly developed administration. It is an island of mixed races. Of its population of 365,000, 299,780 are of Greek extraction and 65,220 Turkish. The British population numbers some 600 only, and are most concentrated in the capital, Nicosia. The languages spoken are Greek and Turkish—outside the six chief towns the English language is unknown, and in the towns only a small minority of the people can speak English.

Dr. Bardswell, on arrival, found that while much was to be heard about the Cyprus tuberculosis problem and its seriousness, there was little definite data available. There is as yet no registration of causes of death other than "from natural or unnatural causes." In consequence the Cyprus Government has no idea as to the annual mortality from tuberculosis. Notification of cases of pulmonary tuberculosis was introduced in 1931, but it is most imperfectly observed. The medical authorities think it probable that only one-quarter of the cases are notified. The introduction of an administrative scheme for the control and treatment of tuberculosis was being held up by the absence of definite knowledge as to the incidence of the disease on the island and the degree to which it is disorganizing the life of its people.

First-hand Study of the Problem

Dr. Bardswell, after a preliminary survey, reported these facts to the Council of the N.A.P.T., and advised that as a preliminary to their offering any advice to the Cyprus Government he should tour the island and try to make good the absence of essential information. The N.A.P.T. and the Cyprus Government concurred in the suggestion.

From January 1 to June 1 Dr. Bardswell and Nurse Jays have been wholly occupied in studying the tuberculosis problem at first hand throughout the island. They encountered many difficulties by no means fully anticipated. The chief of these is the question of language. Dr. Bardswell had to make all his inquiries through an interpreter. Fortunately, so far as Greek is concerned, the language spoken by five-sixths of the people, his interpreter was his N.A.P.T. colleague Nurse Jays, who speaks Greek perfectly. But for this Dr. Bardswell's mission would have been most gravely handicapped,

Another difficulty is the extraordinary and unreasonable fear that Cypriots of all classes have of tuberculosis, which results in the concealment of the disease. Such is the fear that many people will not willingly pass a consumptive patient in the street. The stories current on the island as to the ravages of the disease among the peasantry, who form 70 per cent. of the population, and the social and economic distress suffered by the tuberculous people, have for some time caused much concern to the people of Cyprus and its Government.

Preliminary Impressions

The method of inquiry followed by Dr. Bardswell was to visit the towns and villages throughout the island, to examine as many people suffering from tuberculosis as he and Nurse Jays succeeded in getting access to, and to try and estimate the amount of tuberculous infection present in the towns and villages by "tuberculin-testing" the children for evidence of tuberculosis infection.

In the course of his five months' survey Dr. Bardswell examined 600 persons and tested 8,000 children. His detailed results have yet to be worked out. But it can already be stated that the tuberculosis question is not so grave as has so far been the accepted view.

Though the disease is scattered throughout the island, and is calculated to spread as the primitive people are gradually brought under European influence, there is every hope that it will be effectively controlled by appropriate methods. What lines these measures should take will now be a matter for the serious consideration of the N.A.P.T. Council.

The language difficulty, the low standard of civilization of the bulk of the people, the difficulty of access and transport, the lack of personnel with any knowledge of or training in tuberculous work, the poor financial resources of the Cyprus Government, all contribute to render an efficient anti-tuberculosis scheme in Cyprus much more difficult to devise than in Great Britain.

While certain broad principles hold good for every country, details must be decided by their peculiar conditions. This is the aspect of the Cyprus tuberculosis question which the N.A.P.T., with the results of Dr. Bardswell's survey in its hands, will now proceed to consider. Whatever advice it conveys to the Cyprus authorities, the services of Dr. Bardswell and Nurse Jays will again be given to them for a further period to assist in putting their recommendations into execution, the period of office of these two officers having been extended to June, 1938.

The seventeenth report of the Joint Council of the Order of St. John and the British Red Cross Society covers the year 1936. During that period 259 officers, of whom seventy-four were new cases, received assistance from the Auxiliary Hospitals for Officers Department. The majority of these were suffering from tuberculosis.

Nova et Vetera

ORIGINS OF THE HOSPITAL SYSTEM

[FROM A CORRESPONDENT]

In connexion with the report of the Voluntary Hospitals Commission, which was reviewed in the *Journal* of May 8, it may be interesting to look back into the early origin of our modern hospital system.

London Spitals

When the monasteries were suppressed the Mayor and Commonalty of the City of London prayed the King in 1538 that they might from henceforth have "the order, rule, government, and disposition of the hospitals or spitals, commonly called St. Mary's Spital (Bethlem), St. Bartholomew's Spital, St. Thomas's Spital, and the New Abbey at Tower Hill, with the rents, revenues appertaining to the same for the annual relief of the poor, needy, and sick persons." They reminded the King that the three great spitals were

"founded of good devocion by auncyent fathers and endowed with great possessions and rents only for the relyeff comforte and ayde of the poor and indigent people not being hable to help themselffs and not to the mayntenance of preestes chanons and monks casually lyvyng as they have of late doon nothing regarding the myserable people lyeng in the streets offending every clene person passing by the way wt theyre fylthye and nastye savors."

The prayer of the Corporation was granted. The first spital handed over to the civic authorities was St. Bartholomew's. Soon the revenues became too small to meet the outgoings, and to defray the deficiency the Corporation had the power to levy taxes for its support.

In 1548 an Act was passed by the City Council assessing the City Companies in the sum of 500 marks (£333), to be paid annually to St. Bartholomew's Hospital. This levy was resisted by the livery companies in the year 1712, but the hospital authorities took Chancery proceedings, which resulted in a decree in their favour, and this exists to the present day.

An Early Move in Bristol

Outside of London no provision at all for housing the sick poor appears to have existed. In Queen Elizabeth's reign some effort was made by means of a Poor Law to cope with poverty and unemployment; to replace by local authorities the work formerly carried out by the monasteries. But little or nothing was done for the sick or crippled. The civil wars diverted people's attention even from this effort. After the revolution of 1688 and incidentally after the passing of the Act of Toleration in 1689—which is perhaps the real landmark in the current of national progress—men's thoughts turned in other directions. There was a spiritual awakening; a kind of humanity replaced the bitterness of wars and revolution.

The first move to look after the sick and needy was made in Bristol. It is interesting to record that the first hospital to be established in England after the suppression of the monastic hospitals was not a voluntary hospital in the modern sense, but St. Peter's Hospital in Bristol, which was set up by the Bristol Corporation of the Poor immediately after its establishment in 1696.

At the foundation of the Corporation of the Poor and of St. Peter's Hospital it will be found that a compulsory levy or rate was not the sole source of their revenues. Many private citizens, including Dr. Edward Tyson, moved by the contemplation of the state of the poor in their city, gave large donations. Dr. Thomas Dover gave his services gratuitously to the sick in St. Peter's Hospital. So that at the beginning the Poor Law and its hospital linked together rates and charity in a common purse.

Two Illustrations from Abroad

Two illustrations of somewhat similar plans may be taken from abroad. A good many years ago M. Vancauwenberg founded in the North of France a sanatorium for children suffering from surgical tuberculosis. It is now situated in two branches, one at Berck-sur-Mer and one at Zuydcoote, near Dunkirk. At first the undertaking was supported entirely by voluntary contributions. Its success led to its "adoption" by the State. The effects of this "adoption" as explained by M. Vancauwenberg were that the educational side of the sanatorium, including teachers' salaries, was paid for by the State, and various maintenance charges for the children were borne by departments and communes. The committee of management was no longer self-elected, but the State requested the old committee, with M. Vancauwenberg as chairman, to continue in office with the addition of a few new members to represent public authorities.

Since Professor Calmette joined the committee as the representative of the Département du Nord it may be judged that the presence of such "official" nominees to the board of management occasioned no difficulties. According to M. Vancauwenberg the institution was better off in every way after its "adoption," especially in financial respects; for the voluntary contributions increased rather than diminished, there were new payments by the State and local authorities, the "School" was entirely paid for by the State, and the usefulness and efficiency of the institution was greatly increased.

From Cologne another example could be taken. The Evangelische Krankenhaus was a hospital maintained and supported by the Lutheran community of the city. Voluntary contributions came in generously, and the board of management was chosen by the subscribers. Yet there was a basic grant from the city which amounted to a capitation payment for poor patients. This payment was contingent on the hospital being efficiently conducted. Of this efficiency the medical officer of health for Cologne and the Health Committee were the judges, and in order to keep in close touch with the affairs of the hospital one "official" representative of the Health Committee was on the board of management. In this instance there was no curtailment of voluntary contributions because of municipal finance and control.

Some Reflections

These examples of happy uniting of public and voluntary undertakings need to be closely looked into. The plan may prove impracticable on a large scale. It may turn out that charitable and individual effort has led the way and only served to convince the State of an irresistible demand for adequate medical and social services. Our Navy was evolved out of mere gatherings of merchant shipping armed in haste for particular occasions, our Army from bands of noblemen's retainers, and our Post Office from the attempts of private carriers to serve the public needs. Private undertakings will not cover the country with the comprehensive organization which the nation requires. At some point the gaps must be filled by State institutions, and it should not be impossible to preserve the practice of voluntary contributions, just as St. Bartholomew's has preserved it, within the framework of a municipal institution. The correlation and adaptation of two systems may entail inconveniences. Burke's plan must be followed, so that we "balance inconveniences; we give and take; we remit some rights that we may enjoy others; and we choose rather to be happy citizens than subtle disputants."

Reports of Societies

THE SILICOSIS PROBLEM

Another discussion on silicosis, chiefly from the geochemical standpoint, occupied a special meeting of the Institution of Mining and Metallurgy on June 17. Professor H. V. A. Briscoe of the Royal College of Science, with certain colleagues, had collected from a number of mines in Cornwall dust samples suitable for examination in order to determine the number of dust particles per unit volume of air, and their size, distribution, and chemical and mineral composition in the air as breathed by the underground worker. The results of this investigation were presented in a lengthy and important paper, while Dr. A. Brammall in another paper dealt with geochemistry as applied to the problems of silicosis.

Professor Briscoe stated that a rapid survey of some typical dangerous industrial dusts, using samples collected by settlement and natural impairment of dusts in ventilating ducts in mines, showed that in general these were markedly alkaline. It seemed possible that the relatively high local concentration of alkali produced by dusts in such ducts might help to determine the characteristic effects they had on the lung, for example, by assisting in part to the differences between the phenomena of asbestosis and silicosis. Dr. Brammall, after repeating his own lengthy investigations, said that the earlier suggested that certain substances were extracted in the soluble form from dust-free particles by lung fluid, and that these dissolved compounds of which silica was merely one together with most residuals imposed an abnormal burden on a delicate though not exclusively efficient mechanism.

Those who took part in the discussion from the medical point of view counselled the necessity of caution before accepting a geochemical theory to explain silicosis. Dr. E. L. Middleton of the Home Office deprecated at the present stage any deductions being drawn from the experiments and researches presented so far as they applied to the human problem. He found it difficult to fit the facts presented by the geologists in their study of dusts into the clinical experience of silicosis.

Tissue Reactions

Dr. E. J. King of the British Post-Graduate School, speaking as a biochemist, also added his plea that those working on this subject should take care not to fall into the common modern danger of simplifying the problem too far. They would only be deluding themselves, he said, if they thought that the solubility of dusts, even when determined so nicely as in the experiments described by Dr. Brammall, was an adequate explanation of silicosis, which he regarded as an extremely complex biological phenomenon. Dr. King mentioned that he had once injected soluble salicylic acid twice daily into the ears of rabbits over a period of six months. No fibrosis whatsoever was produced, nothing but a small amount of inflammation periodically. A fairly constant supply of soluble silica produced no biological reaction at all analogous to that which followed the introduction of dust. Moreover, as the late Professor Kettle had constantly stressed, there was an infective process at work in silicosis. Such an infective process always accompanied the condition, and perhaps made it possible. Silicosis might not be a tissue reaction primarily to dust but a tissue reaction to an infection which might be modified to a greater or less extent by the accompaniment of dust. Mr. Haynes of St. Bartholomew's Medical School reminded the meeting of the long period during which dust might remain in the lungs, being ultimately passed out by coughing, or "black spit," as it was called. He remembered in 1919 examining a miner's sputum which contained imbedded coal dust, but the man had not been doing a coal miner for had he had any reason to inhale coal dust since his enlistment in 1914. He could not help feeling that the way in which dusts had been extracted from the lungs and subjected to chemical examination in the pursuit of certain of the investigations into silicosis had been somewhat rough. A much kinder way of obtaining the dust would be by bronchial aspiration, whereby the whole of the protein could be got away and the dust left behind. A treatment rather corrosive to the chemical substances might possibly have removed some of the less chemically resistant ones leaving the more resistant, of which silicate was the outstanding example. Thus a slightly unbalanced picture might have been obtained.

INFANT FEEDING

At a meeting of the Edinburgh Obstetrical Society on June 9, with Dr. Peel Ritchie, the president, in the chair, Dr. H. J. Walker read a paper on the modification of cow's milk for infant feeding.

Dr. Walker said that for subsequently the weakness of the infant was relegated to the medical attendant to the care of the nurse, who was given the responsibility of deciding how the infant was to be fed. How an experiment was usually approached in this regard to the infant being breast-fed, but in case of artificial feeding had to be resorted to there at once became a host of problems demanding the attention of all concerned in its welfare. There was not the slightest reason why one should not be able to feed a baby on cow's milk as successfully as on breast milk, provided one knew how to modify the cow's milk to suit the baby's digestion. For this purpose, despite the degree of opinion existing as to the form in which it should be offered to the infant. He spoke from personal experience of cases in which cow's milk would be modified to suit the infant's digestion, and described certain experiments which had recently been carried out in the bacteriological laboratory of the Simpson Memorial Maternity Pavilion, Edinburgh, in an endeavour to determine the relative merits of the various modifications commonly employed.

Experimental Investigation

These experiments were concerned with the clotting effect of rennin on modified milk. It was pointed out that such simple procedures as dilution with water and boiling had the effect of reducing both the size and toughness of the milk curd, and that the addition of sodium citrate had very little advantage over dilution and boiling. Acidification of milk by the addition of lactic acid prevented the formation of large clots and produced a fine granular precipitate. The addition of partially dextrinized starchy foods to milk did not affect the size and consistency of the clots, since on the addition of rennin these were found to be large and tenacious, closely resembling those of raw milk. If fresh cow's milk were to be used for infant feeding it should be diluted with water, boiled, and have added to it sugar and cream in requisite amounts; the addition of starch was undesirable; citrating and acidifying were unnecessary for normal infants. Two varieties of dried cow's milk were selected for comparison with fresh milk. In one case drying had been carried out by the roller process and in the other by the spray process. When rennin was added to milk dried by the roller process a fine precipitate was formed but no true clotting occurred, whereas in milk dried by the spray process clotting did occur, but the individual curds were comparatively small and soft. In both cases, after gentle shaking to simulate peristaltic action, the appearances produced bore a striking resemblance to that of human milk.

Taking all things into consideration the best available substitute for human milk was a good variety of dried milk, the reasons for this opinion being that such milk was safe in that it was free from tubercle bacilli and pathogenic

organisms; its vitamin and iron content was adequate; it was quickly and easily prepared, thereby reducing the possibility of error to a minimum; and it had been made to resemble human milk to an extent which could never be achieved in the average home. Dried milk, however, was apt to be expensive and was, therefore, often beyond the reach of the very homes where its use would be invaluable—namely, the homes of the harassed, overworked mothers, who had neither the time nor the facilities to make cow's milk safe and digestible for their babies. In conclusion, Dr. Wallace emphasized the fact that the perfect substitute for mother's milk did not exist, and that breast-feeding should still be the aim in all cases.

Local News

ENGLAND AND WALES

British Red Cross Society

The Duke of Gloucester presided at the statutory meeting of the council of the British Red Cross Society on June 10 at 14, Grosvenor Crescent, London, S.W. Before the formal business began the Duke presented the Florence Nightingale Medal to Mrs. Maynard Linden Carter, head of the Nursing Section of the League of Red Cross Societies. The Director-General announced that the four-yearly International Red Cross Conference would be held in London in June, 1938. The Society's annual report was received and approved. This report shows continued expansion both of personnel and activity. Considerable progress has been made in the special training and organization of its membership in order to co-operate with the Government in preparation for defence against aerial warfare, and the regulations have been extended to include the enrolment of air raid precautions reserves. The Clinic for Rheumatism in London is now working to its maximum capacity, and gave 154,378 treatments during 1936. The number of calls on the London Blood Transfusion Service amounted to 5,215, another record over any previous year. In order to facilitate experiments in the relief of certain forms of disease by means of oxygen tents the Society provided twelve tents and placed these at the disposal of twelve teaching hospitals in London. The tests carried out proved of great use, and the Society's action encouraged the use of this valuable method of treatment. The Princess Royal, Commandant-in-Chief, reported that over 800 women members attended the V.A.D. training camp this summer at Winchester, where courses of instruction had been provided. On Coronation Day 944 officers and members were on duty in London in co-operation with the St. John Ambulance Brigade, and dealt with 1,428 cases. The total number of certificates and proficiency badges awarded by the Society for first aid in chemical warfare now amounted to 29,079.

Reduction of Out-patient Waiting

A further step towards the reduction of waiting in out-patient departments has been taken by the Out-patient Arrangements Committee of King Edward's Hospital Fund for London by the issue of a memorandum on time-saving methods in connexion with arrival and registration of out-patients, with notes on other early items of procedure. A previous memorandum dealt with hospital out-patient dispensaries. The Out-patient Arrangements Committee, of which Dr. Morley Fletcher is chairman, was set up as a result of the report of a special King's Fund inquiry into out-patient methods. That report gave a brief outline of time-saving suggestions at every stage of out-patient procedure, and recommended that the King's Fund should follow this up in more detail, so as to assist all hospitals to ascertain whether their own waiting time is capable of reduction, and, if so, how to reduce it. The report states that very much has been and can be done by hospitals to reduce waiting by shortening the interval between the time when patients arrive and the time when they see the doctor. Part I deals with these possibilities under such headings as different times of arrival for different patients; group or class appointments; sorting; sifting; general supervision. Part II deals in detail with registration. It describes a system based on the latest improvements in such matters as the number and design of the forms, their use at the registry, at the various departments and at the dispensary, and indexing and filing. Part III gives a list of salient points in a form intended to be of use to a hospital reviewing its procedure. Copies of the memorandum may be obtained from the publishers, Messrs. Geo. Barber and Son, price 1½d. net, post free.

Birmingham Health Congress

About 2,000 people will be in Birmingham for the health congress which is to be held there by the Royal Sanitary Institute from July 12 to 17. It is expected that a record number of delegates will be appointed to attend from Governments and local authorities in all parts of the world. The Earl of Dudley will be installed as president of the Congress on July 12 and will deliver his inaugural address. The congress luncheon will be held at the Grand Hotel on Monday, July 12, at 1 p.m., and the congress dinner at the same place on Thursday, July 15, at 7.45 p.m. The Minister of Health has promised to address a general session on July 13. The comprehensive list of papers to be read includes such subjects as the future of our population, the national fitness campaign, development of the maternity service, care of the pre-school child, housing progress and prospects, slum clearance, roads and public health, and protection of bulk milk. Altogether there will be fifty addresses and papers. At the exhibition in the Bingley Hall manufacturers from all parts of the country will be represented, and there will be exhibits illustrating municipal hygiene and health and comfort in the home.

SCOTLAND

Medical Education

Speaking at Edinburgh on June 17 on the national drive for health and nutrition, Dr. Chalmers Watson said that the Government programme to promote a great national drive in the interests of health, nutrition, and physical education had done little or nothing to secure the interest and co-operation of general practitioners, who ought to be able to play an important part in the Government's scheme. Much had been heard lately about improved national health and increased longevity, but statistical evidence, on which these statements were based, must be interpreted with caution; employers of labour and others interested would do well to note that the Department of Health in its last report revealed the fact that the cost of sick benefit for insured persons last year showed an increase of 10 per cent. over the previous year. Medical education was to-day more closely related to medical treatment than it used to be, but a continuation of this relationship would depend largely upon a progressive attitude on the part of the universities. The Scottish Committee on Health Services had reported last autumn that unless medical training was preventive in outlook many of the committee's recommendations for the development of health policy would be stultified. In 1932 the League of Nations had gone into this matter, and had published several volumes recording the opinions of medical representatives of various countries. Their main conclusions had been that reform had long been called for, but that universities and teaching schools were either unable or unwilling to move in the matter. It had been announced by the medical faculty of Edinburgh University that a

comprehensive series of changes in the curriculum was about to be made to bring medical education more into line with modern requirements, but traditions died hard, and the changes that were necessary would not be easily secured. A more efficient medical curriculum would undoubtedly involve increased expenditure, but that expenditure would be amply repaid by the greater value of an improved curriculum.

Dundee Royal Infirmary

At the annual meeting of governors of Dundee Royal Infirmary on June 14 the report which was submitted showed that the ordinary income for the previous year had amounted to £38,393, which was an increase of £334 upon that of 1935. There had, however, been an increase in expenditure of £1,642, and the deficit on the year's working amounted to £7,527. Mr. David Ayr, the chairman, said that the financial position had caused grave concern and could be improved only by the increased generosity of all subscribers. It was hoped that the public, who valued the work carried on efficiently by voluntary hospitals would show their appreciation by an increase in both contributions and legacies and substantial donations.

Correspondence

Population Investigation Committee

SIR,—We should be grateful if you would give us the opportunity of correcting, in your columns, a misconception which has arisen about one of the activities of the above committee. At present there is little accurate information available as to the amount of physical and sterile marriage in this country; we are still in doubt as to whether this is increasing or decreasing, and as to the part which it plays in the decline in fertility. With the object of obtaining accurate data on this and other aspects of the problem of fertility our committee has prepared a questionnaire of which very misleading accounts have been published in the Press.

We should like to point out (1) that the questionnaire has been produced on the sole initiative of our committee, and that neither the Ministry of Health, the General Register Office, nor any other organization is in any way responsible for it, and (2) that it will not be sent direct to parents or other members of the public. We are not yet in a position to give full particulars of the procedure by which we hope to obtain the desired information.—We are, etc.,

HARDLEY HOLLAND.
C. P. BLACKER.

London, S.W.1, June 24

The Age Incidence and Sex Incidence of Milk-borne Typhoid

SIR,—An interesting comparison may be made of the figures for the Bournemouth epidemic given by Professor R. M. Picken (*Journal*, June 19, p. 1284), and those recorded by Dr. R. W. Johnstone (1910)[1] for the Folkestone Urban District during the fourteen years 1896–1909. A total of 357 cases of typhoid fever occurred in that period, and of these 206 were traced to milk infected by one individual, who was eventually proved to be a typhoid carrier. Among the milk-infected cases children under 15 numbered seventy-eight, or 37.9 per cent., while among those presumably infected in other ways the percentage of children under 15 was 27.5.

In the age groups over 15 the sex ratio in the milk-infected patients was 100 males to 220 females, and in the others 100 males to 105 females. As the proportion of males to females over the age of 15 in Folkestone at the census of 1901 was 100 to 151, the contrast between the numbers in the milk-infected group as compared with the other is striking. It is noteworthy that at Bournemouth, where the milk was apparently infected for about a month, and at Folkestone, where infection from a single source persisted for fourteen years, the incidence on adult females should have increased so greatly.

Study of such data as are available suggests that, especially, speaking, milk-borne infection falls more heavily on women and children, but there are so many exceptions to this rule that the observations are of little practical value when applied to the investigation of any given epidemic. Most of us will agree with Professor Picken's view that "this method of different along the lines of epidemiology is in practice quite useless" (Lancet, etc.,

Bournemouth, June 21 LEON ERRINGTON.

Technique in Knee-joint Operations

SIR,—I was surprised to read Mr. A. S. Blundell Barker's comments on the technique employed by Mr. Eric Lloyd in operations on the knee-joint (*Journal*, June 12, p. 1259). But knowledge of pronation has always existed that although the surface of the skin may be rendered sterile, the deeper tissues may still harbour organisms. For many years it has been my practice to swab the deeper tissues of the skin exposed by the direct approach of the knee-joint with a weak solution of iodine, and I have never known this to cause any harm. I have also found that the addition of a few drops of iodine to the irrigating fluid used during the operation has always been beneficial.

Surely success is the best test to prove that these elements the possibility of infection from the deeper tissues of the skin by skipping from the edges? Does Mr. Barker believe that all such tissues should be swabbed with blood no organisms can pass? This question raises a practical point in technique which applies to all branches of surgery, and one which I had intended to make the subject of a special communication to the *Journal*. I am grateful to Mr. Eric Lloyd for returning to it in his address on "Technique in Operations on the Knee-joint." I am, etc.,

Birmingham, June 20 NATHANIEL DEAN.

When to Operate in Appendicitis

SIR,—I should be glad to know what is the general opinion of surgeons on the question of cases of inflamed appendix with abscess formation. To-day I sent a case of this type into hospital.

Briefly, the history, which varies little in these illnesses, is one of a six-day illness commencing with pain in the right iliac fossa six days ago. The patient had no gastric symptoms till the third day, when he was sick and continued so till a simple bismuth mixture allayed matters within twenty-four hours. His temperature began to rise, and varied between 99.8° and 100°; the bowels moved daily without any aperient. To-day, the sixth day, a palpable lump in the appendix area was evident; he had anorexia; the pain still remained as it had done, but the tenderness was much more marked. The diagnosis was obvious.

His wife came to see me four hours after his admission to hospital with the report that the surgeon had decided not to operate. I was surprised to hear this; and to placate her and to ensure that the patient's condition had been investigated I 'phoned the hospital and spoke to the medical officer

[1] Johnstone, R. W. (1910). *Reports to the Local Government Board on Public Health and Medical Subjects*, New Series, No. 41.

in charge of the wards. He agreed with the diagnosis, but said the custom in that hospital was to wait, leaving the question of operation to some future time, and meanwhile keeping a close eye on the patient's condition.

Of course, one of three things will happen: (1) Absorption of the inflammatory products with resultant adhesions. (2) A circumscribed abscess cavity with a gangrenous appendix floating in the products of its own decomposition. (3) Extension of the inflammatory process with peritonitis, followed by immediate and grave operation.

My reason for writing is to indicate that there are different schools of opinion on the correct procedure. I have known similar cases, sent to different hospitals, and still have vivid memories of the trenchant and almost libellous comments of two surgeons on the characters and qualifications of the doctors who had attended and delayed sending the patients into hospital. My own Edinburgh training was directed to early and immediate operation. It is not for me to go into the arguments pro and con in this matter. But in view of the evidently divergent opinions held I should like an authoritative statement as to what the majority of surgeons practise in these types of appendix cases.—I am, etc.,

Bedfont, Middlesex, June 24. J. HEPBURN.

"What is Osteopathy?"

SIR,—I am glad Dr. Kelman Macdonald has made it quite clear (*Journal*, June 19, p. 1284) that he and I do not agree as to the interpretation of osteopathic findings—that was my hope when I answered his letter. But I am in entire agreement with him when he says that "the physiological circulatory conditions prevailing around a joint and the pathological findings supervening in joint injury are facts which are not altered by what interpretation" I put on them or by what he reads into them. I have never at any time suggested otherwise, and it is difficult to understand why he elects to answer my letter with such an implication. I only claim that my interpretation is based on physiological and pathological findings which in the main are accepted by almost the entire scientific world, and his is based on osteopathic pathology, which is not.—I am, etc.,

London, W.1, June 22. MORTON SMART.

Ionization for Hay Fever

SIR,—Although feeling much sympathy for my friend Mr. Vlasto on his non-success in treatment of hay fever by zinc ionization, I am unable to explain it. The technique is simple for a rhinologist, although I can quite believe that electrotherapeutists who are not familiar with the anatomy of the nose might have many failures.

On the other hand, in ionization for suppurative otitis media the selection of cases and the technique are of the greatest importance. For attic cases with a tiny perforation the method is quite useless, whereas for cases in which the tympanum is accessible through a good-sized perforation in the lower part of the membrane zinc ionization with proper technique gives the most dramatic success.

With regard to my own experience of ionization for "hay fever," last year I treated seventeen private cases. Of these, two were done rather late in the season, and although they cleared up satisfactorily they might have been nearing the end of their seasonal misery; so I will not include them. Of the other fifteen, two were free from symptoms after one ionization, two were almost free; nine cases were nearly symptom-free after two ionizations, and were free after a third. One patient was very little better, and one showed no improvement. The results of my hospital cases were very similar.

In my experience zinc ionization gives better results than any other method. An objection to it is that it is an empirical treatment directed to the nose. We do not know how it acts. For tympanic sepsis, however, this treatment is not empirical. The ionization produces a coagulation necrosis of the organisms in the middle ear, and thus sterilizes the cavity. For this reason the applications of this treatment in the nose and ear should be carefully discriminated and their results not confused.

Vasomotor rhinitis does not yield many successes. One gets an occasional very pleasing cure from ionization, but not the high proportion of cures that one gets in hay fever.—I am, etc.,

Guildford, June 26. T. B. JOBSON.

SIR,—Mr. Michael Vlasto questions the value of ionization in hay fever. I think the chief value of zinc ionization of the nasal mucosa is to reduce the sensitiveness of the mucous membrane in all those complaints which give rise to paroxysmal sneezing, whether from hypersensitiveness to pollen or to any of the air-borne dusts, or from bacterial causes. At times this may be sufficient to relieve the symptoms. But in hay fever the whole of the patient, every square inch of skin, every drop of blood, is hypersensitive to the pollen and can be proved to be hypersensitive by the Prausnitz-Kustner reaction (passive transfer and the dermal reactions). This being so, it would seem fatuous to rely simply upon treatment of the nose in a complaint in which every cell of the body is sensitized.

In treating those afflicted by immoderate sneezing the first maxim is to discover the cause by the dermal reactions. Next, to desensitize the patient with the protein that may be at fault—pollen, horsehair, orris root, etc. If the nasal mucosa is inordinately sensitive to a probe and the sneezing reflex easily produced with redness of the eyes, then ionization or cauterization is of great value, always allowing that the possibility of the irritation being due to a microbic infection has been ruled out.—I am, etc.,

London, W.1, June 28. FRANK COKE.

SIR,—Mr. Vlasto, in his letter in the last issue of the *Journal*, asks whether others shared his experience with intranasal ionization for so-called hay fever.

In our special ionization clinic at the Chest Hospital, Margaret Street, over 800 patients have received treatment during the last three months, mainly for seasonal rhinitis. It is difficult to assess the relative proportions of cases which suffer from rhinorrhoea precipitated by pollen and those in which the rhinorrhoea is produced by other factors, such as metabolic disorders, climatic influences, psychopathic vasomotor disturbances, etc. In our experience a large proportion of the cases benefit from ionization. There is no doubt that the therapeutic effect of the ionization largely depends on the technique employed.

Twelve years' experience of this special type of treatment and the advantage of examining and observing such a large number of cases this season have enabled me to obtain improved results by modifying the technique. I intend as soon as possible to publish in detail the technique used at our clinic and to give complete statistical results of this treatment. I hope that others will do the same so that the value of this treatment can be satisfactorily assessed.—I am, etc.,

London, W.1, June 28. PHILIP FRANKLIN, F.R.C.S.

Animal Pathology: Puerperal Infection

SIR,—I was very pleased to read the letter of Dr. T. Hare on the subject of animal pathology in the *Journal* of June 12 (p. 1229). We must all hope with him that some day an institute of comparative pathology will be founded, where "the diseases of animals can be studied for the service of medicine," for until medicine works in closer co-operation with veterinary science and agriculture its progress will be slower than it need be. The further study of diseases in animals will undoubtedly throw light on the pathology of obscure diseases in man. I should like to state here an interesting problem bearing on this point.

Some time ago my fox terrier, aged 10, had her fourth or fifth litter of puppies; as we had another dog she was confined in her kennel inside the garage. After a difficult labour, in which I had to assist her, two pups were born dead, and one survived. The two dead pups were removed and buried, the placenta and debris swept out of the garage on to some grass outside. On the second day she was very ill, would not take her food, shivered, and was very restless and anxious to get out. The next day her condition was worse; she was weaker, would take no food, and her restlessness and anxiety to get out was so great that, in spite of her weakness, I decided to let her do so. To my astonishment she started searching in the grass outside the garage, and when she had found the placenta immediately ate it and then went straight back to her kennel. Next day she was much better, and in a few days quite well again.

Those are the facts of the case, and I was fortunate to be able to observe them so closely. It is well known that certain animals always eat the placenta immediately after birth, and farmers say the animals will not settle down properly until they have done so. It is also well known that other mammals do not eat the placenta; why is there this difference? I always presumed that the animal ate its placenta because it was there and looked like something to eat; but here was a dog whose placenta was removed, who was becoming very ill, and was making frantic efforts to get out with the sole object of consuming it, and who after doing so made a rapid recovery. The only conclusion I can come to is that the placenta contains something which is vitally necessary to the animal at that particular time, while those animals which do not eat it absorb *in utero* the necessary substances, which are probably in the nature of antibodies or antitoxins to streptococcal infections.

If this is so it will help to elucidate the puzzling problem of puerperal infections in women. As is well known there are two types of parturient women, those who show no sign of puerperal infection whatever the environment or operative intervention and those who develop puerperal fever under the very best possible conditions and even when no vaginal examinations are made. It is important to remember that in subsequent confinements under precisely similar conditions the results may be reversed, and so this can only be due to some state in the woman herself. The whole question is, What gives immunity or lack of it?

My idea is that most women, in the last few weeks of pregnancy, absorb certain substances from the placenta which are antitoxins. In other women, or in the same woman at another time, there is failure to absorb these substances in sufficient quantities, and so they become an easy prey to infection. These "non-protected" patients require injections of placental extract during the last two or three weeks before the confinement to replace this deficiency. This suggestion has been strengthened by the reports that recently, both in England and America, placental extract has been used to immunize children against measles and scarlet fever.

The only other question that arises is whether it is possible to tell definitely in the last few weeks of pregnancy whether a woman has this "protection" or not. I suggest the application of the Dick test; if a positive reaction occurs showing there is no antitoxin circulating in the blood the injection of placental extract should begin at once, and should continue until the test becomes negative, or even during the first week of the puerperium.

Perhaps Dr. Hare would be able to carry out experiments to confirm or disprove these ideas at the Research Laboratories of the Veterinary College. I should be extremely interested to hear the results of any such investigation.—I am, etc.,

Isle of Anglesey, June 21. J. L. MOIR.

Maternal Mortality and Sepsis

SIR,—I am sorry for Sir Kingsley Wood. In your leading article of June 19 you suggest that the Minister has offered only the second best where the best is called for. He has had to depend on his medical officers, who by direction have furnished him with a report on an investigation into maternal mortality. I can only imagine Sir Kingsley Wood's feelings when he finds that report differing little in essential recommendations from many which have gone before it.

The most important factor concerned in the maternal death rate is septic infection. I will limit my remarks to this one cause. A crop of excuses has sprung up lately to account for the sustained high incidence in mortality rates. The latest refers to the alleged increase in the number of miscarriages. Why are they so prone to become septic? I surmise that most of them are performed by persons who understand the risk they run when a case goes wrong and they are well acquainted with modern methods of asepsis. Surely there must be something wrong with the modern method.

Other excuses are set out in detail, such as inadequate training, insufficient ante-natal care, and, best of all, the lack of the advice and direction of specialists. When we know that the worst figures are supplied from institutions in which specialists walk which way can we turn? Again, I have heard specialists of high standing discount the claims of slums for proverbial immunity. As the figures from these quarters, or rather the registered births, are included in the domiciliary class, I am not convinced that the immunity does not exist; in fact, I believe that the immunity of the slum woman is due to her immunity from interference by a medical attendant. When we read of the Aberdeen report commending a maternity organization in which midwives should conduct all normal deliveries, I feel that I am in good company. As this recommendation struck a severe blow at family practice, it has been toned down somewhat in the latest reports, and no wonder. To me it is the greatest declaration of defeat and failure that I have known the medical profession to make.

Now let me shed a little light. In the Prefatory Note to the latest report to the Minister of Health by the Chief Medical Officer, figures are quoted from the old Edinburgh Maternity Hospital (1823-44) showing a mortality of 19 per 1,000 due mainly to puerperal sepsis. How we have improved! I will quote some figures too. The figures I quote refer not to a mere 3,906 deliveries, but to upwards of 10,000 recorded by Collins about one

hundred years earlier, in which there was a mortality of 0.53 per cent., *not one of which was due to sepsis.* Collins painted the walls, floors and bedsteads, and soaked the linen, his hands and instruments with a solution of chloride of lime. Hence the miracle. He was thus the first obstetrician to use the antiseptic method, and crude as it was it was effective. Need I declare myself a disciple of Lister? So I can boast that sepsis has no terrors for me. And so I repeat, I am sorry for Sir Kingsley Wood. —I am, etc.,

A. C. F. HALFORD, M.D., F.R.A.C.S.

London, June 24.

The Second Best—in Housing

SIR,—I was glad to see your criticism of the policies pursued by the Ministry of Health in the various spheres of housing, maternity, ophthalmic benefit, clinics, and occupation—all subjects of vital national concern in which all general medical practitioners must be interested. My only criticism is that the Ministry is "let off" too mildly. The mere presentation of figures does not reveal the truth. The history of the National Government's actions in regard to the housing problem is one of lamentable failure. In 1931 it cut down housing expenditure. In 1932 the Wheatley subsidy was stopped, and in 1933 it discouraged building even without a subsidy. In 1933 the Rent Restriction Act abolished rent control of middle-class housing, and so there was a rush of speculative builders. *This Act fixed 1938 for the rent control of workers' houses. In 1934 the Government guaranteed* part of the mortgages for building by private enterprise and the rich building societies! Thus it made a new situation profitable to profiteers in spite of the fact that the Minister of Health (Sir Hilton Young, now Lord Kennet) admitted the fact known to all that there was a great shortage of houses *to let* for the lower-paid workers. This gave expansion to the less satisfactory building by speculative builders for the middle classes as that for the lower-paid workers became less a commercial proposition. Public discontent at this policy forced the Government to do something, and that something showed no vision—namely, the Housing Act of 1935, or as some people have termed it the "overcrowding" Act! The main points of this Act are that it defines "overcrowding," compels a survey *on the definition;* after January 1, 1937, makes "overcrowding" (as defined) an offence; reintroduces a subsidy; and, mark, alters the basis of compensation to land and property owners. The definition of "overcrowding" is the weakest link and *real* overcrowding slips through it. The definition sets up no standard of *separate* living accommodation, which the London survey, the Merseyside survey, or the census of 1931 adopted. The result is that the severe (or real) overcrowding is untouched by the Act, and the so-called figures presented as to its existence and amelioration are mere eye-wash. Many anomalies as to the constitution of a family in a given area making for "overcrowding" could be given. Children under 10 years are counted half an adult and those under 1 year are not counted at all. The overcrowding survey of England and Wales revealed 341,554 families being "overcrowded" by the definition in the Act, 283,844 on the verge of it, and 623,429 families who escape the definition by *half a unit!* Yet the Minister of Health wants to know why some women won't have babies. The general practitioner could give him the correct reply.—I am, etc.,

A. G. NEWELL, M.D., D.P.H.

Ilford, June 21.

Courses in Individual Psychology

SIR,—As a consequence of the sudden death of Professor Adler at Aberdeen on May 28 it has become necessary to remodel the programme of lectures and vacation courses in individual psychology arranged for this summer.

Dr. Alexandra Adler, Professor Adler's daughter and herself a brilliant exponent of individual psychology, has very courageously undertaken to carry out, as far as possible, the programme arranged for her father. Certain adjustments and cancellations have, however, been necessary. The programme is now as follows: lecture course, non-resident, in the British Medical Association Hall, Edinburgh, June 21 to July 2; vacation course at University Hall, Liverpool, July 7 to 12; vacation course at Bishop Otter College, Chichester, Sussex, July 17 to 26.

We, the undersigned, being convinced of the great value of individual psychology in throwing light on the fundamental problems of human life in an age of great perplexity, would appeal to the medical and teaching professions, and the Church and parents especially for as large a measure of support as possible for these courses. This would be the finest tribute that could be paid to the memory of a great benefactor of the human race, who devoted his life to freeing men and women from the burdens of misconception and misunderstanding which lie so heavily upon the human family.

We wish to take this opportunity of thanking the University and City of Aberdeen for having done everything in their power to honour the memory of Professor Adler by arranging an official funeral service in the chapel of King's College on June 2.—We are, etc.,

NINA HAMILTON AND BRANDON.
ALBERT LIVERPOOL.
ISABEL MARGESSON.
ALFRED BEIT.
PHYLLIS BOTTOME.
IAN L. FLEMING.
ELIZABETH HOARE,
Chairman, Adler Vacation Courses.

London, W.8, June 21.

Pulmonary Embolism in an Infant

SIR,—The following notes on a case of pulmonary embolism in an infant of 7 months may be worthy of publication, since this condition is rarely found under the age of 20.

A healthy child aged 7 months was admitted to the Peterborough and District Memorial Hospital on May 26, 1937, under the care of Dr. E. A. Holmes, for the radical cure of a right inguinal hernia, and the operation was performed under ether on the following day.

The wound healed well, and subsequent progress was satisfactory until the ninth day after operation, when the temperature at 5 p.m. was found to be 103° F., with a pulse rate of 130, although the patient otherwise appeared comfortable. At 9.15 that evening he suddenly became very collapsed and cyanosed, with distressing dyspnoea. Respirations were 70 a minute, and the pulse was almost imperceptible. The child's colour improved with the administration of oxygen and stimulants, but the orthopnoea continued, and death occurred in about forty minutes. At the necropsy a long coiled thrombus occupying the left branch of the pulmonary artery was found.

I am indebted to Dr. Holmes for permission to record this case.—I am, etc.,

H. W. CHADFIELD, M.R.C.S.

Peterborough and District Memorial Hospital, June 14.

Medico-Legal

ATTACK BY MENTAL DEFECTIVE

We noted in these columns (May 1, p. 944) the hearing of an appeal against an application by Mrs. Bertha Holgate and her husband, William Rennie Holgate, for leave to bring an action against the Lancashire Mental Hospitals Board, and Dr. F. A. Gill, the superintendent, and Dr. G. S. Robinson, the deputy superintendent, of the Calderstones Institution, a home for mental defectives maintained by the Board. The court gave permission, its decision was upheld on appeal, and the action was tried at Liverpool Assizes on June 10 before Mr. Justice Lewis and a jury.

The facts were not in dispute: a moral defective named John Lawson had been several times convicted of criminal violence, and had for some years been confined at Rampton, a State institution. He was transferred to Calderstones as considerably improved, and after a time was released on licence under the personal supervision of his brother. The licence was signed by the deputy superintendent with the consent of two members of the committee of management, and was renewed. While out on his second period he called at the home of the Holgates, and when Mrs. Holgate had her back to him he attacked her savagely with a billet of wood, inflicting very severe injuries on her. He was convicted at the assizes and sent to a criminal lunatic asylum.[1] Mrs. Holgate and her husband brought an action against the Joint Board and the medical men for negligence in licensing Lawson. Mr. Thomas Burke, a member of the Board, said that when the managing committee had agreed to license Lawson, the patient's brother had assured them that he would have Lawson under his personal supervision. Lawson's condition had improved so far, and he had shown no violent tendencies for so long, that it was considered safe to allow him out for a month. There was in any case nothing to prevent an inmate of Calderstones from walking out of the grounds. Miss M. L. K. Jones, another member of the committee, said that she had been present when the committee renewed Lawson's licence for his second period of absence on the assurance that his conduct during the first period had been satisfactory. Cross-examined, she said that she had not known that Lawson had been convicted of a series of savage and criminal offences. When the licence had been renewed the committee had not had his dossier before them, but it would have been before the committee when it originally granted leave of absence.

Dr. Gill said that he had left Dr. Robertson in charge while he was on official leave. He knew that Lawson's brother was a respectable working man, but had not appreciated that the house was only in charge of a daughter during the day. Dr. Robertson said that at the time he signed the certificates for Lawson's leave he believed that to do so was quite safe. It was his duty, according to the terms of his appointment, to sign the certificates. To give mental defectives on licence official supervision would be a tremendous task. Dr. Gill had never been consulted about Lawson's leave. The jury found that the Joint Board and both medical officers had been guilty of negligence in allowing Lawson to go out on licence, and awarded Mr. Holgate £708, including £208 out-of-pocket expenses, and Mrs. Holgate £3,500.

From the reports in the *Times* and the *Liverpool Daily Post*, to which we are indebted for the foregoing account of the hearing, it appears that Dr. Robertson, while acting as superintendent in Dr. Gill's place and with the consent of two members of the responsible committee, licensed Lawson to go out under supervision, for the efficacy of which he had only the word of Lawson's brother, knowing Lawson's record and mental constitution. Accommodation in mental institutions is very limited, and every local authority naturally wishes to let out on licence as many patients as it safely can. The judgement of its officers is very rarely at fault. Sir Patrick Hastings, K.C., who conducted the case for Mr. and Mrs. Holgate, maintained that only the superintendent could sign a licence, and that Dr. Robertson could not do so in his place. As this point was not specifically dealt with in the jury's finding it remains undecided, but as a matter of practice an institution would be in an impossible position if it were not permitted to appoint an officer to act as superintendent during the substantive superintendent's period of leave. The finding seems to have been very hard on Dr. Gill, for he was apparently never consulted about Lawson's leave and did not even know that the licence had been extended, though he granted it originally. As Dr. Gill collapsed while giving evidence, and was not therefore able to complete his testimony, certain aspects of his responsibility could not be properly investigated by Sir Patrick Hastings. The case, however, seems to fall into the category in which *res ipsa loquitur*—the event speaks for itself. It is settled law that if a thing in the keeping of A causes damage to the person or property of another in circumstances which suggest negligence unless they are explained away, A will have to pay damages unless he can give a satisfactory explanation. The jury here were not satisfied that the Board and its medical officers had done their best to ensure that Lawson could be safely let out. In future committees managing institutions for mental defectives and persons of unsound mind will have to realize that they license at their peril patients with a record of violent conduct.

DENTAL PRACTICE BY MEDICAL MEN

When dental practice was regulated by the Dentists Act, 1921, the right of medical men to practise all kinds of medicine and surgery was preserved by Section 1 (3) (*a*), which lays down that nothing in the section shall prevent the practice of dentistry by a registered medical practitioner. A number of doctors, though probably not very many, practise dentistry by virtue of their medical qualifications, though they are not on the *Dentists Register*. They may be surprised to learn that, though there is nothing in law to prevent them practising dentistry, they are not recognized as dentists under the National Health Insurance Acts, and cannot receive pay for dental services to insured persons under the Acts and Regulations.

This rule was settled by Mr. Justice Simonds in the Chancery Division on June 18, in an action in which Dr. C. A. Bynoe asked him to grant an injunction against the General Federation of Trade Unions Approved Society to prevent them from writing or saying that he was not entitled to give dental services and receive payment under the National Health Insurance Acts, 1924–8, or the Dental Benefit Regulations, 1930, Art. 21 (1). Dr. Bynoe, who is on the *Medical Register* but not on the *Dentists Register*, treated a member of this approved society in February, 1935, and sent in a dental letter with an account for £1 12s. 6d. The society did not pay this amount, but on February 6, 1935, wrote to the patient saying that they had received the estimate but were unable to pay the charges or deal with the dental letter as Dr. Bynoe's name was not on the *Dentists Register*; they suggested that the patient should obtain an estimate from another dentist. Dr. Bynoe maintained that they implied by these words that he was not qualified to give dental services or to receive payment for them from the society.

The learned judge explained in his judgement that the National Health Insurance Act, 1924, s. 75, allowed societies to distribute additional benefit when they had a certified disposable surplus. The amending Act of 1928, s. 16 (3) allows regulations to be made for the administration of schemes provided that they do not restrict the right of any insured person to obtain treatment from any practitioner with whom the society has made arrangements. The Dental Benefit Regulations, 1930, Art. 2, define "dentist" as a person on the *Dentists Register*. Art. 21 provides that a member can obtain dental treatment from any dentist who is prepared to provide it for a certain fee. The learned judge therefore found it

quite clear that Dr. Bynoe was not entitled to give treatment under the regulations and receive payment from the approved society for it, for he was not a person with whom arrangements had been made to give such treatment in accordance with the regulations. He remarked that, while there might be persons who, though not on the *Dentists Register*, were quite competent to give dental treatment, he could quite understand the Minister of Health confining the right to give dental treatment under the Acts to persons on the *Dentists Register*.

ACKNOWLEDGEMENT BY SIGNAL

A testator may validly execute a will by directing someone else to sign it in his presence. The law requires, however, that the testator shall "acknowledge" the signature—that is, shall do something to show the witnesses that he understands that the other person is signing for him. When the will is proved the court will ask for evidence that the signature was made in the presence of the testator and by his direction and that he acknowledged it. The acknowledgement need not even be verbal, and sometimes indeed a patient near death is too weak to speak. He may then indicate his acknowledgement by any sign so long as its meaning is unmistakable. Recently the President of the Probate Division, Sir F. Boyd Merriman, pronounced for the will of a woman whose doctor signed it for her in the presence of witnesses. She had almost lost the use of her right hand, and at her request the doctor read out the contents of the will to her and asked her to squeeze his hand if she approved it and wanted him to sign it on her behalf. She squeezed his hand accordingly and two witnesses attested the signature. She died about three weeks later. The short report, for which we are indebted to the *Times* of June 22, does not state why the testatrix did not acknowledge the signature verbally. At all events the action for probate was undefended and the validity of the acknowledgement was not questioned.

Obituary

We regret to record the death on June 19 in London of Dr. MURDOCH MACKINNON, formerly of Nairobi, after two days' illness. Dr. MacKinnon received his medical education in Edinburgh and King's College, London. He graduated M.B., Ch.B.Ed. in 1905, and proceeded M.D. three years later. In 1911, after serving as casualty physician at St. Mary's Hospital, he obtained the diploma D.P.H.Oxon. He had conducted a private practice in Nairobi, Kenya Colony, for twenty-two years, and had been medical officer to the Government school for eighteen years. He took advantage of the facilities for research thus made available to him, and in 1923 published in the *Journal of Tropical Medicine and Hygiene* an account of the influence of education on the physical and mental development of European children in the highlands of Kenya; this attracted considerable attention in view of the practical questions involved and of the value of the statistical comparison he made between children educated at home and abroad. Another article by him was published in 1929 in the *Kenya and East African Medical Journal*, and dealt with rheumatic fever and chorea in that country. Dr. MacKinnon joined the British Medical Association in 1909, and was president of the Kenya Branch in 1926–7 and again in 1935. In the last-named year he returned to England, and had latterly been in practice at Twickenham.

The death occurred at Alloa on June 21 of Dr. TUACH MACKENZIE, who had just retired from the post of physician-superintendent of Dundee Mental Hospital. William Tuach Mackenzie was born in Ross-shire in 1871, and after taking a medical course at Aberdeen University graduated M.B., Ch.B. in 1898, proceeding to the degree of M.D. in 1903, when he submitted a thesis on acromegaly. After holding resident posts in the Aberdeen Royal Infirmary and the Rotunda Hospital, Dublin, he was appointed to the charge of pauper lunatics in Giggleswick Union, West Riding, Yorkshire. In 1899 he was appointed deputy-superintendent of Dundee Mental Hospital, and four years later succeeded the late Dr. James Rorie as physician-superintendent of this institution, a post which he held until shortly before his death. He was also lecturer in mental diseases at St. Andrews University, and was a member of the British Medical Association and of the Royal Medico-Psychological Association. In his earlier days Dr. Tuach Mackenzie took much interest in athletics, having been as a student a member of the Aberdeen University XV and swimming champion of the University for three successive years. He was also a member of the Royal and Ancient Golf Club, St. Andrews, for twenty years. He joined the British Medical Association nearly twenty-five years ago.

In the death of PAUL IEUAN WATKIN, M.A., M.R.C.S., L.R.C.P., on June 20, the Stratford Division of the British Medical Association has lost a consistent and tireless worker, an inspiring personality, and a true friend. Graduating from Christ Church, Oxford, he became lecturer in physics at St. Thomas's Hospital, later proceeding to his medical diplomas, for which he studied at the London Hospital. Some thirty years ago he settled in practice in Canning Town, and worked there steadily till his death, becoming a figure well beloved in all his professional and social work. Professionally Dr. Watkin's chief interest was in dermatology; this found expression in his devoted work at St. Mary's Hospital, Plaistow, where he became physician in charge of the skin department. Socially his interests were profound and varied. In his undergraduate days at Oxford he became a resident at the Mansfield House Settlement, beginning thus an active association which lasted till his death. From 1915 onwards he represented the West Ham Borough Council on the West Ham Insurance Committee, and later was a co-opted member of the maternity and child welfare committee of the council. For many years a member of the Executive Committee of the Stratford Division, he became chairman of the Division for two years, starting in 1933. His participation in local affairs of the Association was regular, persistent, and always valuable. Broad in outlook and culture, jovial yet severe and well-balanced, kindly to all whatever their standing, Paul Watkin was one of our "elder statesmen." He can receive no higher tribute than that paid by a doctor-patient of his to the writer when he heard of this death: "Well, one of the landmarks of West Ham has gone."

The Rochdale Division of the British Medical Association has sustained a great loss by the death of Dr. SAMUEL WILSON, chairman of the Division 1936–7. To the deep regret of the members illness prevented Wilson from presiding over meetings of the Division after July of last year. In September he was compelled to relinquish his work, and he died on May 29 in an ambulance while on his way home to Rochdale from his seaside bungalow in North Wales, where he had been staying for some time. Wilson was born at Maybole, Ayrshire, and was a student at Glasgow University, taking the degrees of M.A. and, in 1907, M.B., Ch.B. He held resident posts at Belvedere and Ruchill Fever Hospitals, Glasgow, and in 1908 came as house-surgeon to Rochdale Infirmary. After holding this post for about eighteen months he became assistant to Dr. Wallace of Rochdale, taking the practice over shortly afterwards on the retirement of his principal. For over a quarter of a century he carried on a very large private and panel practice single-handed, except for a period of three years from 1923, when a nephew assisted him. The numbers on his panel kept at the maximum

figure! Consequently Wilson's leisure time was scanty. When work permitted he enjoyed a game of golf, usually with his lifelong friend and colleague, the present chairman of the Division. Their encounters on the Rochdale links during the last twenty-five years have become part of the history (and legend) of the club. Wilson's other relaxation was reading—philosophy, biography, and the classics being his choice. In the enjoyment of his books he stole many hours from the night. At the funeral service at Rochdale Parish Church and the burial at Rochdale Cemetery on June 2 a large number of his patients and medical colleagues gathered to show their affection and regard. Dr. Wilson is survived by a widow, two daughters, and two sons; both the latter are medical students.

Universities and Colleges

UNIVERSITY OF OXFORD

At a congregation held on June 24 the degree of Bachelor of Medicine (B.M.) was conferred on N. H. Martin.

UNIVERSITY OF CAMBRIDGE

At a congregation held on June 22 the following medical degrees were conferred:

M.B., B.CHIR.—W. H. Phillipps, *C. N. Pulvertaft, N. T. Holden, J. A. Seymour-Jones.

M.B.—R. C. F. Catterall, G. N. St. J. Hallett, A. R. Pope, M. S. M. Rayner, C. J. F. Coombs, *H. W. Sadlier, *K. M. Mayall.

* By proxy.

The following candidates have been approved at the examinations indicated:

THIRD M.B.—*Part I (Surgery, Midwifery, and Gynaecology)*: E. W. O. Adkins, G. E. Adkins, R. F. Ashwin, T. M. Banham, C. F. Barwell, P. F. Barwood, R. D. D. Birdwood, A. W. Box, E. E. Bullock, J. F. H. Bulman, G. A. Burfield, O. J. Curl, J. K. Denham, R. C. S. Dick, H. G. Dowler, H. L. Ellis, T. J. Fairbank, A. L. Fawdry, N. Feiwel, A. Garcés, E. A. G. Goldie, A. C. F. Green, J. L. Griffith, J. E. Hardwick-Smith, S. W. G. Hargrove, N. J. P. Hewlings, J. H. S. Hopkins, R. T. Johnson, J. S. Joly, H. S. Kellett, P. Kelly, A. Leese, P. F. Malim, R. W. Mason, J. H. Moir, W. E. D. Moore, K. S. Mullard, W. A. Nicholson, A. P. Norman, W. E. Owens, G. R. C. Peatfield, P. A. T. Phibbs, E. H. D. Phillips C. G. Rob, D. Rubin, G. Sheers, J. F. Stokes, D. C. Sturdy, D. J. D. Torrens, R. L. Townsend, S. C. Truelove, W. B. Waterfall, P. H. Willcox, J. M. G. Wilson, P. R. Wilson, D. E. Yarrow, M. D. Young. *Women:* V. E. A. Sykes. *Part II (Principles and Practice of Physic, Pathology, and Pharmacology)*: C. D. Anderson, R. A. Andrews, R. F. Ashwin, E. F. Aubert, J. L. W. Ball, T. M. Banham, R. C. B. Barbor, P. F. Barwood, I. G. Braddon, H. A. Brook, J. F. H. Bulman, C. T. A. Burgess, L. H. Cane, N. F. Coghill, J. O. Collin, F. S. Cosh, F. M. Crawshaw, A. C. Cunliffe, R. C. S. Dick, C. M. Dickins, H. G. Dowler, R. Edwards, W. H. Ekin, E. A. Evans, E. M. Evans, N. Feiwel, J. N. Fell, C. H. C. Ferguson, G. M. Fleming, E. B. French, J. C. Gilson, C. E. D. H. Goodhart, I. C. A. D. P. Graham, I. A. Guest, H. Haigh, S. G. Hamilton, J. N. Horne, W. H. R. Jeremy, J. S. Joly, P. Kidd, A. B. Lintott, T. P. H. McKelvey, R. W. Markham, J. H. Moir, M. D. Molesworth, C. R. Morison, W. G. Murray-Browne, T. P. Myles, R. C. Neville, L. B. Paling, A. K. Pardhy, M. T. Parker, E. A. Pask, J. P. Reidy, G. O. Richardson, C. G. Scorer, C. J. S. Sergel, K. M. M. Sheldon, J. P. Singer, R. M. Solomon, R. S. Stevens, A. W. Stewart, J. F. Stokes, R. F. Tredgold, W. B. Waterfall, R. W. Watts, D. O. Wharton, B. D. Whitworth, E. H. L. Wigram, L. A. C. Wood, H. R. Wynne, G. E. Yardley. *Women:* M. B. Billington, G. M. S. Caldwell, A. C. Clark, C. E. Peaker.

UNIVERSITY OF LONDON

At a meeting of the Senate held on June 23, with the Vice-Chancellor, Mr. H. L. Eason, M.D., M.S., in the chair, Sir Robert Pickard, D.Sc., F.R.S., was elected Vice-Chancellor for the remainder of the year 1936-7 and for 1937-8. A cordial vote of thanks was passed to Mr. Eason for the great services he has rendered to the University during his tenure of the office of Vice-Chancellor. Mr. Eason took up his duties as Principal of the University on July 1.

Professor L. S. Dudgeon, F.R.C.P., has been appointed as from July 1 a representative of the General Medical Schools on the Senate for the remainder of the period 1934-8.

Sir Ernest Graham-Little, M.P., M.D., has been re-elected a member of the University Court for a further term of five years from October, 1937.

UNIVERSITY OF MANCHESTER

The Vice-Chancellor, Professor J. S. B. Stopford, M.D., F.R.S., has intimated to Senate and Council his desire to be relieved of the duties of the chair of anatomy, in view of the increasing responsibilities of his administrative work, and Mr. Frederic Wood Jones, D.Sc., F.R.C.S., F.R.S., at present professor of anatomy in the University of Melbourne, has accepted an invitation to the chair in succession to Professor Stopford, and will take up his duties in January, 1938.

UNIVERSITY OF WALES

WELSH NATIONAL SCHOOL OF MEDICINE

The following candidates for the degrees of M.B., Ch.B. have satisfied the examiners in the subjects indicated:

OBSTETRICS AND GYNAECOLOGY.—D. W. Abse, S. W. Beswick, Alice Davies, Miriam E. Davies, D. G. Evans, W. G. Miles, A. H. Millard, Mary D. Owen, W. L. Ll. Rees, R. Tipple, Emily K. Williams, Mary Williams.

UNIVERSITY OF GLASGOW

At a ceremony of graduation held on June 25 the following degrees were conferred:

M.D.—E. D. Cooper (with honours), S. Lazurus (with high commendation), A. Dick.

PH.D.—D. Matta, M.B., Ch.B. (*in absentia*).

M.B., CH.B.—A. M. Thomson.

The Asher Asher Gold Medal in Laryngology and Rhinology was awarded to D. Christison.

The Services

HONORARY PHYSICIAN TO THE KING

Lieutenant-Colonel A. G. Biggam, O.B.E., R.A.M.C., has been appointed Honorary Physician to the King and promoted to Brevet Colonel, vice Colonel J. Heatly-Spencer, C.B.E., late R.A.M.C., who has retired.

VOLUNTARY AID DETACHMENTS

The latest official returns of the progress made in the organization of Voluntary Aid Detachments show that 154 men's and 1,060 women's detachments, comprising a total membership of 30,942, have received recognition by the War Office. During the past year there has been an increase of 39 detachments and 1,673 members. Of the present membership 6,832 have undertaken the "mobile" obligation.

The county areas in England which have a total membership of 500 or over are: County of London, 1,785; East Lancashire, 1,761; Norfolk, 1,489; Hampshire, 1,278; Yorkshire (West Riding), 1,155; Surrey, 1,110; Devonshire, 1,030; Sussex, 1,005; Somerset, 982; West Lancashire, 976; Cheshire, 974; Essex, 865; Kent, 759; Yorkshire (North Riding), 713; Gloucestershire, 551; Nottinghamshire, 525; Lincolnshire, 519; Staffordshire, 500.

In Scotland there are 160 detachments, with a total membership of 4,132, of whom 1,091 are "mobile" members. There are 75 detachments in Wales, the total membership being 1,704, of whom 340 are "mobile" members.

The present scheme for Voluntary Aid Detachments was inaugurated in 1923, and is designed to supplement the medical services of the Naval, Military, and Air Forces in time of war. "Mobile" members are required to give an undertaking that, in the event of the embodiment of the Territorial Army, they are prepared to serve with the medical services either at home or abroad. "Immobile" members undertake to serve within reach of their own homes.

Medical Notes in Parliament

In the House of Lords on June 28 the Methylated Spirits (Scotland) Bill was read the third time, and the Factories Bill, which has had a first reading on June 22, was read a second time. On June 29 the Physical Training and Recreation Bill was read a second time after a discussion in which Viscount Dawson of Penn joined.

The House of Commons this week considered the Finance Bill and the proposed increase in the Exchange Equalization Fund. On June 22 it gave a third reading to the Factories Bill. The Children and Young Persons (Scotland) Bill passed through the committee of the House without amendment on June 23 and was read a third time. It had already passed the House of Lords. On June 28 the Hydrogen Cyanide (Fumigation) Bill was read a second time.

In the Commons on June 29 a financial resolution, upon which the Bill containing the Government's agricultural proposals will be founded, was agreed to in committee. Mr. W. S. Morrison, in explaining the proposals, dealt with the attack to be made on disease in animals and poultry, and said that a centralized veterinary service for the whole of Great Britain would be created.

A meeting of the Parliamentary Medical Committee was summoned for July 1.

Drainage of Trade Premises

A Standing Committee of the House of Commons considered on two nights the Public Health (Drainage) of Trade Premises Bill. Mr. BERNAYS (Parliamentary Secretary to the Ministry of Health) moved to insert a provision in Clause 1 to maintain that part of the existing law which prohibits the discharge of petroleum spirit and calcium carbide into a public sewer. The committee agreed to the amendment.

On Clause 2 (Special Restriction on Discharge of Trade Effluent) Mr. ARTHUR REED moved that the word "stating" be used instead of the word "specifying" in the obligation on all factories to give to the local authority information on their effluents. Sir KINGSLEY WOOD said he appreciated that in some cases it might be difficult to specify the exact chemical composition of a trade effluent. As long as the local authorities had a general indication they would be able to carry out their duties under the Act. He was prepared to accept the amendment, which was then agreed to.

Mr. QUIBELL said the Bill empowered local authorities to prevent certain trade effluents from going into the sewers. He wished to know what a trade should do with such an effluent. Some local authorities would not allow a pit into which oil or petrol had been emptied to be connected with the sewer. In such a case the trader tipped the liquid out of a pit and it finally found its way into a gulley and thence into the sewer. Sir KINGSLEY WOOD said machinery would be provided under the Bill which would enable the local authority to require that before a trade effluent entered the sewer there should be eliminated any such constituent thereof as might be specified in the by-laws. A general code would be secured which would apply all over the country.

On Clause 4 (Exemption) Mr. H. G. WILLIAMS moved a long amendment dealing with premises where a drain or sewer communicating with the public sewer or cesspool had been provided with a new drain or sewer in lieu thereof. Mr. Williams said the amendment would provide that the rights that the trader possessed in the old drain should be given him in the new one. The amendment would deal with the quantity of effluent which the trader might wish to carry to his treatment plant. Sir KINGSLEY WOOD said he had no criticism to make of the amendment, and the committee agreed to it.

Sir KINGSLEY WOOD moved to provide that the consent of a local authority to the discharge into a sewer of any liquid produced solely in the course of laundering articles should not be necessary for the purpose of the Act. He said this did not exempt liquids produced in the course of cleaning or dyeing. The committee agreed to the amendment. Sir Kingsley refused, however, to accept an amendment moved by Mr. Morgan which proposed to exempt the discharge into a sewer of any liquid produced in the course of washing down a slaughterhouse, and Mr. Morgan withdrew the amendment.

Consideration of the Bill was completed and it was reported to the House.

Factories Bill

The report stage of the Factories Bill began in the House of Commons on June 15 with consideration of new clauses. Sir SAMUEL HOARE moved a new clause dealing with washing facilities. He said that under the present Factory Act facilities were provided only in trades and industries which were liable to special dangers. The Bill, as introduced, had proposed to extend these requirements to trades in which there might be a large amount of dirt and dust. In committee on the Bill members of all parties thought the scope was too narrow and the Government gave an undertaking that a new clause would be introduced. The House would see that under the clause which he now moved facilities would be provided where they were needed and could be reasonably supplied.

Mr. RHYS DAVIES pointed out that these facilities under the new clause were to be provided "in any factory where any employed persons are accustomed to take their meals at the factories." He wished the Government was not so timid. After further discussion and an appeal by several members that the new clause should be withdrawn for reconsideration, Mr. MESSER spoke of the dirty hands of French polishers, which could not be washed clean with soap and water. In that industry dermatitis resulted from the use of turpentine, etc., and a man who had dermatitis might wash in the same bowl as other men, and possibly spread the disease. In some places the workers washed their hands in methylated spirit to get rid of the polish, which was not a good thing. Sir SAMUEL HOARE said he would consider that point, and undertook to redraft the clause on more general lines. The clause was withdrawn.

A new clause, dealing with accommodation for clothing not worn during working hours and the provision of arrangements for drying such clothing was read a second time.

PROTECTION OF THE EYES

Mr. GEOFFREY LLOYD moved a new clause (Protection of eyes in certain processes), which ran:

"In the case of any such process as may be specified by regulations of the Secretary of State, being a process which involves a special risk of injury to the eyes from particles or fragments thrown off in the course of the process, suitable goggles or effective screens shall be provided to protect the eyes of the persons employed in the process."

Mr. SHORT hoped the Home Secretary would ensure that employers saw their workmen used these necessary defences. Mr. MCLAREN said that in industries where men sweated the goggles became corroded, and when these goggles fitted badly across the bridge of the nose serious inflammation might occur. It was not enough to provide suitable goggles; the individual must be suited. Mr. LLOYD replied that the fitting of goggles was important, but screens would be prescribed wherever possible. The clause was read a second time.

Mr. BANFIELD moved a new clause to prohibit night work in bakehouses. He said Great Britain was the only country which had not abolished night baking. Sir SAMUEL HOARE said the Committee on Night Baking had not issued its report and he was not in a position to make a statement for or against the case which Mr. Banfield had put. When the report was received the Government would at once give attention to it and decide what action, if any, it should take. The proposed new clause was defeated by 228 to 125.

Colonel SANDEMAN ALLEN moved a new clause authorizing a variation of the hours to be worked in laundries. The clause was carried by 200 to 117 and was added to the Bill.

OVERCROWDING AND VENTILATION

The House then proceeded to consider the clauses of the Bill as received from standing committee. On Clause 1 (Cleanliness) Mr. RHYS DAVIES moved to provide that the weekly cleaning of the floor of every workroom should be done at a time (if any) when work was not going on in the workroom. Mr. GARRO JONES said that unless sweeping was done hygienically it was more menacing to the health of the workers than neglect of any sweeping at all. The amendment was withdrawn and a technical amendment dealing with Clause 2 (Overcrowding) was added to the Bill.

The House agreed to an amendment proposed by Sir SAMUEL HOARE, who explained that in the Bill as amended by it inspectors were authorized to insist on mechanical ventilation at once in cases where that was needed; secondly, after a period of five years mechanical ventilation would be generally compulsory; and, thirdly, the concessions allowed for existing factories in the same occupation were to be subject to a definite time limit of ten years. Mr. LLOYD put forward an amendment authorizing the chief inspector to accept in the subsection any workroom in which explosive materials were manufactured or handled. The amendment was carried after discussion by 228 to 112 and the House adjourned.

On resumption of the debate on June 16 the House accepted an amendment moved by Colonel SANDEMAN ALLEN to Clause 2 (Overcrowding). This amendment provided that where a room contained a gallery, the gallery should be treated for the purposes of this section as if it were partitioned off from the remainder and formed a separate room. An amendment by Mr. RIDLEY was also accepted, which provided that unless the inspector for the district otherwise allowed it should be the duty of the employer to post a notice in the workroom stating the number of employees who might be engaged there at one time.

POWERS OF SANITARY INSPECTORS

On Clause 8 (Enforcement by district councils of certain provisions of Part 1) Major MILNER moved an amendment. He said the clause provided that in any of the succeeding provisions of the Bill there should be substituted for reference to the inspector a reference to the medical officer of health. The purpose of his amendment was to add the words "or sanitary inspector." The clauses related to cleanliness, overcrowding, temperature, ventilation, drainage, and sanitary conveniences. These things were peculiarly the functions of the sanitary inspector. If the clause went through as it stood, the House would take away from sanitary inspectors the power they at present had under the Factory and Workshops Act of 1901. Without this amendment, when the sanitary inspector came along, even under the direction of a medical officer of health, a factory owner could tell him that he had no authority to come into the factory.

Mr. T. M. COOPER said the clause was not to determine which officer of a local authority was to perform certain duties relating to inspection. Its purpose was to transfer to a named officer of a local authority certain powers which, under the scheme of factory legislation, were specifically conferred on the inspector. The amendment would extend the powers of sanitary inspectors beyond those they now enjoyed. It would be out of harmony with the system of local government to suggest that the medical officer of health should act on a report of a sanitary inspector. The Sanitary Officers Order of 1926 was among the administrative regulations and controlled the relations of the medical officers of health to the sanitary inspectors. The sanitary inspector worked under the supervision and direction of the medical officer of health and was a subordinate person. The amendment was negatived. On a motion of Mr. LLOYD amendments were made on Clause 14 (Other machinery).

On Clause 21 (Training and supervision of young persons working at dangerous machines) Mr. BURKE moved an amendment. He said the clause empowered the Minister to prescribe certain machines to which the clause should apply. The Labour Opposition contended modern factories were of such a character that the whole place was dangerous; the machines to be described would in the main be those which had been involved in accidents. If the amendment was accepted, safety-first instructions would be part of the terms of employment of every young person. The rate of accidents among boys was 38 per cent. above the rate for older persons and 65 per cent. above in the case of girls. Mr. LLOYD said the Home Secretary intended to make full use of the power given in the clause, and after the Bill was passed the Home Office would issue lists of machines which came under the terms of the clause. The amendment was withdrawn.

Amendments were made on a motion of Mr. LLOYD in Clause 22 (Hoists and lifts) and on the motion of Mr. GRAHAM WHITE in Clause 23 (Chains, ropes, and lifting tackle).

On Clause 25 (Construction and maintenance of floors, passages, stairs, and ladders) Mr. MARSHALL moved to provide that where the floor of any workroom was apt to become slippery effective steps should be taken to prevent accidents. Mr. LLOYD said it would be unwise to insert in a statute of criminal offences a requirement which gave occupiers of factories only a vague indication of what they were to do. It would be better to leave it to the Secretary of State under Clause 59 when making regulations for dangerous trades to insert provisions dealing with slipperiness of floors. The amendment was withdrawn.

On Clause 27 (Precautions in places where dangerous fumes are liable to be present) drafting amendments were made, and Mr. WHITE moved an amendment prescribing that the manhole in tank waggons and other mobile plant should be not less than 16 in. long and 14 in. wide. The amendment was accepted.

FIRST-AID TRAINING

On Clause 45 (First-aid) Sir SAMUEL HOARE moved to leave out the restriction to factories using mechanical power of the obligation to provide first-aid equipment. This was accepted, as was also an amendment providing that in factories employing fifty persons or upwards the person in charge of the first-aid equipment should be trained in first-aid treatment.

On Clause 52 (Underground rooms) Mr. SHORT moved to provide that work should not be carried on in any underground room "unless it is certified by the inspector for the district to be suitable for the purpose on hygienic grounds and in particular as regards construction, light, ventilation, and adequate means of escape in case of fire." Sir SAMUEL HOARE said if inspectors had to certify every one of these underground rooms, although they knew that many reached a comparatively high standard of accommodation, they would not have time to do more urgent work. He asked the House not to accept the amendment. The amendment was defeated by 209 to 134. A further amendment by Mr. SILVERMAN to insist upon a height of 8 ft. 6 in. from the floor to the ceiling of underground workrooms was also negatived.

Mr. LLOYD moved to provide that in the case of any underground room which at the commencement of the Act did not form part of a factory or was not used as a workroom in a factory other than for storage the occupier should, before the room was used as a workroom, give notice in the prescribed form to the inspector for the district, and should not use the room for any process of a hot, wet, or dusty nature or which was liable to give off any fume without the consent in writing of the inspector of the district. The amendment was agreed to.

On Clause 53 (Basement bakehouses) Mr. BANFIELD moved to provide that no such bakehouse should be used after five years from the passing of the Act. He said there had been no new underground bakehouses since 1901, and in that year the majority of the existing underground bakehouses were already old. The amendment was defeated by 187 to 125, and a further amendment was inserted to provide for the examination in the year of commencement of the Act and in every fifth year succeeding that, by every district council, of each basement bakehouse in respect of which a certificate of suitability had been issued. If the council is not satisfied with the result of the examination, they shall give notice that the certificate

shall cease to have effect after the expiration of not less than one month and that the basement bakehouse shall not thereafter be used as a bakehouse.

The discussion of the Bill was adjourned.

EMPLOYMENT OF YOUNG PERSONS

When consideration of the Bill was resumed on June 17, Mr. RHYS DAVIES, on Clause 69 (General conditions as to hours of employment of women and young persons), moved to insert a provision that it should not be lawful to employ a young person under the age of 15 in a factory. Sir SAMUEL HOARE said we were reaching a time when the school-leaving age would go up. Mr. Rhys Davies did not believe in the possibility of beneficial employment for those under 15, but that was not the view of the House when it passed the Education Act under which it was possible, with rigid safeguards, to make exemptions for beneficial employment. Lord EUSTACE PERCY said that, broadly speaking, factory employment was incompatible with education during the years up to 15. Mr. GEOFFREY LLOYD quoted a report from an industrial district which declared that the great majority of the girls and more than half of the boys leaving school requested factory work. He reminded the House that under the Education Act the education authority in granting leave to take up such work would have to consider the health and physical condition of the child. The amendment was defeated by 207 to 137.

Mr. SHORT moved to make the conditions of hours of employment general by leaving out the reference to women and young persons in Clause 69. The amendment was defeated by 193 to 125. Mr. DOBBIE moved to reduce the maximum hours of weekly work for women and young persons from 48 to 40. Mr. LESLIE said the report of the chief inspector showed that accidents to young persons had risen from 3 per cent. in 1928 to 22 per cent. in 1935 owing in the main to the long hours which these young people had to work. Sir SAMUEL HOARE said if the House reduced the hours of 1,500,000 women and 1,000,000 young persons under 18 from 48 to 40, it would dislocate industrial life. So far as women were concerned, the Government did not feel justified on grounds of health and safety in reducing their hours of labour to 40. The amendment was defeated by 195 to 128.

The House adopted an amendment proposed by Mr. LLOYD to ensure that in the case of young persons under 16 the period of employment should not end later than 6 p.m. He said it might necessitate a reorganization in some London workshops.

Technical amendments were made dealing with overtime in trades where there is exceptional pressure for a short time in the year and also with hours of work in factories where milk is treated and in tenement factories.

DUTIES OF EXAMINING SURGEONS

On Clause 124 (Appointment and duties of examining surgeons) Mr. RHYS DAVIES moved to provide that, subject to the consent of the employed person concerned, the examining surgeon should have the right to inspect the medical records of the medical practitioner employed by the occupier of the factory. He said a point of etiquette might arise on that inspection, and the Labour Opposition proposed that the examining surgeon for this purpose should be paramount over the medical officer employed by the firm. Mr. LLOYD said this proposal depended on the doctor employed by the firm having kept his records at the factory in a form in which they could be read by other people. A more serious objection was that the examining surgeon should have the right to a roving inquiry into the records of another practitioner irrespective of the precise scope of his duties under the Act. It would be more practicable to leave the matter to be settled between the two doctors. The Home Secretary would bear the point in mind under subsection 5, which provided that he might regulate the duties of the examining surgeon. Mr. Rhys Davies withdrew his amendment.

Mr. ELLIS SMITH moved to insert in Clause 124 that where any person was liable to contract an industrial disease from any process carried on in a factory, the examining surgeon should examine such person at least once a month during working hours, and keep a record of such examinations for the inspector. He said his object was to secure that further steps would be taken by the Home Office to deal with silicosis, asbestosis, dermatitis, and other industrial diseases.

Mr. LLOYD said the term "industrial disease" was too vague. It would mean that a vast number of examinations would have to be made. A month was too rigid a period for the examination. In the lead poisoning regulations the time between the periodical examinations varied according to the process. Monthly examinations would not be appropriate for silicosis, which developed slowly. Under the silicosis provisions of the Workmen's Compensation Act periodical examinations were made, but the intervals varied according to the process and the concentration of silica dust in a particular process. For silicosis a technical and skilled diagnosis was required which the ordinary doctor was not capable of carrying out. Mr. Ellis Smith should consider whether there was a particular case in the potteries—the industry with which he was connected—for requiring periodical examination in connexion with additional processes. The Home Office would look carefully into any further information on that matter. With regard to dermatitis a monthly examination would not be frequent enough. The workman should have his hands examined daily, perhaps as he went into the works, and the practical method of dealing with the question would be for the Home Secretary to make regulations under Clause 59—the dangerous trades clause. He reminded Mr. Ellis Smith that under Clause 11 the Home Secretary had for the first time power to require the medical supervision of workers in all factories in certain circumstances. Mr. Ellis Smith then withdrew his amendment and the report stage was completed.

The Bill was read a third time in the House on June 22, Sir Francis Fremantle being among those who took part in the debate.

Methylated Spirits Bill

The Methylated Spirits (Scotland) Bill, which had passed the House of Commons and secured a second reading in the House of Lords, was taken in committee of that House on June 17. Lord ASKWITH moved a series of amendments, which, he said, had been redrafted in the Scottish Office, and he understood that the Government and the promoters of the Bill were prepared to accept them. The object was to avoid double listing and dual authority. The chemists in Great Britain were, by an Act passed in 1933, placed under the Lord President of the Council and under the Statutory Committee. Certain provisions in the Bill would be applied by this Committee. The proposal embodied in the amendments was that while local authorities and the resellers of surgical spirit or methylated spirits would be controlled by the Bill, doctors or chemists, who were already under stringent regulations, should be treated by authorities whose powers should continue to exist.

The House then agreed without discussion to the amendment proposed by Lord Askwith, including one to add to Clause 1 the following proviso:

"Nothing in the foregoing provisions of this section shall apply to surgical spirit sold by an authorized seller of poisons on registered premises or supplied by a duly qualified medical practitioner, registered dentist, or registered veterinary surgeon for the purposes respectively specified in subsection (1) of Section 19 of the Pharmacy and Poisons Act, 1933, if the requirements of subsections (2) and (3) of the said section are complied with in relation to such sale or supply of surgical spirit in like manner as if it were a medicine."

The committee stage was concluded.

On June 22 the Bill passed the report stage in the House of Lords.

Health Services Debate

In the House of Commons on June 18 the estimates for the Ministry of Health were further discussed, and on this occasion the votes put down included that for the Board of Control. Mr. ARTHUR GREENWOOD opened the debate by discussing housing and the working of the Overcrowding Act.

MENTAL TREATMENT CRITICIZED

Mrs. TATE raised the question of the treatment of mental disease. A few days previously, she said, the Minister of Health opened a new mental hospital at Runwell which cost £650,000 to build and would hold about 1,000 people. It was a very fine place, and people who went there would receive care and attention according to the present ideas of what the mentally afflicted should receive. The problem, however, was whether such enormous expenditure was necessary. Taking the average of the country the cost of a mentally treated person was about 28s. each weekly after buildings, land, staff, and so forth were paid for. Yet a newspaper had said that for £75,000 this country could have the finest mental research laboratory in the world. What was needed was a realization of the enormous proportion of cases of mental disease of wholly physical origin which would never have required mental treatment if proper treatment had been given in the early stages. She herself did a certain amount of certifying, and the people she had to see fell into two categories. In the first were those for whom nothing could be done beyond keeping them in comfortable conditions and seeing that for the rest of their lives they did as little harm as possible. In the other category were those human beings who, until the present or some previous attack, were often intelligent, valuable members of the community, not even old, sometimes in early life. They had to be certified, and if they went to Shenley or Runwell doubtless were examined and had proper treatment. But why were they not examined and treated long before they reached the stage of having an attack? Almost nothing was being done in this country to treat mental diseases in their early stages. Many affected persons went to an asylum where they would be lucky if they had any medical attention worthy of the name and if any real examination into the physical side of the illness was ever made.

"APPALLING" MENTAL HOSPITALS

Part 2 of the report of the Board of Control was an unsatisfactory document. It pointed out little real difference between the good hospitals and the bad, and the bad were almost too appalling to be believed. It showed that in many mental hospitals there were between 300 and 400 patients to each doctor. In many of them there was practically no dental treatment whatever, and the sanitary conveniences would not be allowed in any other building. Of one hospital the report said it was rather a pity that the washing arrangements were such that it was only possible for patients to be washed once

tnight. There were recommendations that the scrubbing-
ies used for the kitchen tables and the lavatory pans
d be better if they were not identical, and for patients
ave individual toothbrushes. Money spent on such cons
ns was money poured down the drain. There must be
: accommodation in many parts of the country, but were
to build gigantic colonies such as Shenley and Runwell at
lling expense or set up clinics for the treatment of disease
s early stages? If these hospitals had to be enlarged
d it not be done with greater effect at a smaller cost?
ll the counties of England country houses were for sale
h nobody was likely to take. Surely they could take
: of these houses of moderate size, modernize them, put
rtain class of mental patient into them, and have a panel
siting doctors.

"NERVE CLINICS"

rs. Tate asked the Minister to suggest to local authorities
der extension of the work which was being done at Park
al, Middlesex, where there was a clinic for treatment of
ous patients. A stigma attached to the name "mental
ise." Therefore call these centres "nerve clinics," do
ything to see that anyone suffering from nervous disease
ided a nerve clinic, and ensure that when they went there
whole physical condition would be properly investigated.
ple who had been discharged after receiving mental treat-
t complained to her of lack of human understanding. It
not always the fault of the staff. In many hospitals it
almost impossible to get any staff, and the first improve-
t to be made in mental hospitals where conditions were
should be an improvement in the conditions under which the staff lived and worked. Mrs. Tate begged the Minister, when the head of a hospital which had been a bad hospital left, not to let the second in command be promoted just because he had been there a long time. The country welcomed the fact that St. George's Hospital was attempting to undertake treatment of mental and nervous disorders in the early stage. That should be compulsory in every State hospital and should be urged on every voluntary hospital.

MATERNAL AND TUBERCULOSIS MORTALITY IN WALES

Mr. JAMES GRIFFITHS said he found alarming facts in the reports upon the health of the people in Wales. He appealed to the Minister to assist Wales more generously to develop her social services. Of the ten worst administrative counties for maternal mortality eight were Welsh; of the ten worst in respect of mortality from tuberculosis six were Welsh; of the thirty worst for overcrowding eleven were Welsh. These were not separate problems but really one problem. In 1924-33 maternal mortality in Wales exceeded the maternal mortality in England by 35 per cent. The rate in the special areas had been substantially increasing, and South Wales generally had had 10 years of poverty and unemployment. Of 665 mothers examined at infant welfare centres in Wales 30 per cent. were anaemic and in an emaciated condition. Out of thirteen administrative counties in Wales eight had no ante-natal clinic, yet they were among the counties which showed the worst maternity rate. The best services in the world would be inadequate to offset the general poverty and overcrowding, the low incomes, and the low standard of life.

Mr. LOVAT FRASER said children were living in workhouses to-day contrary to the regulation which provided that no child over the age of 3 should live in a workhouse for longer than six weeks. There was still need for vigilance to prevent cruelty in children's homes.

Captain ELLISTON regretted that Sir Kingsley Wood gave the House no assurance about the promised long-term milk policy. Outbreaks during recent years of typhoid, paratyphoid, scarlet fever, and septic throats had been recognized by the Ministry as directly due to milk-borne infection. The case for the pasteurization of milk was scientifically irrefutable. The real opposition to the protection of the public against milk-borne disease was dictated by economic considerations because pasteurization would involve some producer-retailers in extra costs. He had recently brought to the notice of the Ministry the fact that large quantities of boned beef were imported in unrecognizable cuts with lesions removed that might indicate disease. Large consignments of this beef were brought to the City of London market, but a proper inspection was impossible. The Ministry had given assurance that the system of inspection at the port of origin was absolutely reliable, but he had a report in his hand by Mr. Ross Grant, the Australian veterinary officer, which seemed an admission that boned beef enjoyed no respect in Australia. Nearly 2,000 tons of that beef came to England each month, more than half of it from Australia. Was it too late for the amendment of the Public Health (Imported Foods) Regulations which were to come into force on January 1, 1938?

VOLUNTARY HEALTH ORGANIZATIONS

Capt. Elliston wondered how far the Ministry was wise in delegating its responsibilities to voluntary bodies. An example of this practice was found in relation to rheumatic disease, a malady which accounted for one-sixth of the expenditure on national health insurance and caused 50 per cent. of heart disease. The Empire Rheumatic Council, a voluntary organization, was spending its time endeavouring to raise funds to carry on its work. The Minister ought to help this organization by finding funds and by stimulating local authorities to establish clinics in connexion with public baths. He should also induce those authorities to provide wards and research units in Poor Law hospitals which they had taken over. The Population Investigation Committee was another voluntary organization which had no staff and no funds. A matter so urgent for the future of the race really called for immediate appointment of a Royal Commission backed up by the resources of every Government Department concerned.

SIR KINGSLEY WOOD'S REPLY

Sir KINGSLEY WOOD, dealing with the anticipated decline in population in reply to the debate, said what was first needed was research of a scientific kind—more facts and a more satisfactory and informatory method of getting population statistics. Complete information could only be obtained by the census or by the registration system. The next census would not be taken until 1941, and it was better to build up annually a continuous volume of statistics. Therefore the registration system was best for the purpose, but existing powers only permitted information relating to births to be obtained for entry in the birth register, and full copies could be obtained by the public. A proposal to enter up in the register information of the duration of the marriage and the number of children previously born of it was open to objection. The objection would be met if it were arranged for the necessary particulars to be given to the registrar confidentially not for entry in the public register but for statistical purposes only. He would examine this matter. If it were adopted legislation would be required.

VENEREAL DISEASE: VISIT TO SCANDINAVIA

Sir Francis Fremantle and Mr. Grenfell had referred (in the earlier debate) to the measures taken in relation to venereal disease in certain Scandinavian countries. The scheme for prevention and treatment of venereal diseases in this country was based on the recommendations of the Royal Commission which reported in 1916. The Commission reported against any system of compulsory notification or treatment on the ground that the element of compulsion would deter some people from consulting a doctor or attending at a centre. They had built up about 180 centres in England and Wales, and the total number of attendancies by patients each year was well in excess of 3,000,000. In 1935 the total number of persons dealt with for the first time at the centres was 98,000, and of those as many as 36,230 were found not to be suffering from venereal disease. That showed that the centres were readily used by persons apprehensive of having contracted the disease. The number of fresh cases of syphilis attending the centres had steadily fallen from some 23,000 in 1930 to 19,000 in 1935. In 1920 the number of these cases was about 42,800. That striking evidence was confirmed by the death rate for infants under 1 year of age certified as due to syphilis. The number of cases of gonorrhoea attending the centres had not varied very much in recent years, and it was commonly supposed that many sufferers from this disease, especially women, did not receive proper treatment either at a centre or from a private doctor. The present policy and belief was that the use of these centres by persons suffering in this way could best be secured by judicious education and propaganda on the importance of seeking early and skilled treatment for this disease. The anti-venereal disease measures in Scandinavian countries differed essentially in having notification and compulsory treatment. In this country there had been a decline of 36 per cent. in the figures of fresh syphilitic infections since 1931. Between 1924 and 1929 there was apparently little or no decline, but since then the decline had been remarkable, and the rate of fresh infection with syphilis, now in the region of 160 per million of the population, compared favourably with the rate of 220 per million in Denmark. The Minister felt, however, that a further special study of one or more of the Scandinavian systems might yield useful results. The Secretary for Scotland and he were arranging for one medical officer from each of the two departments, together with an administrative officer experienced in venereal diseases, to visit Scandinavia at an early date and report. They would consider the extension of that inquiry to Holland where there was voluntary treatment.

MENTAL DISORDER AND DEFECT

Sir Kingsley claimed that good progress was being made in human progressive treatment of the mentally disordered and mentally defective people of the country. Mrs. Tate had read extracts from the report of the Board of Control regarding bad cases, but that report recorded a far greater number of good cases, and in no other country was there so frank a statement of the position in mental institutions. Directly officers of the Department ascertained these cases they wrote to the authorities concerned, called upon them to remedy the conditions complained of, and later saw what steps had been taken. Three things were required in the mental services of the country. First there must be constant vigilance in the conduct and control of these institutions. Secondly, he attached great importance to efforts to secure the right type of nurse. Thirdly, it was essential to investigate vigorously any instance of ill usage or bad treatment. He thought there was need for further research into causes of mental affliction, and he had recently appointed a committee under Lord Radnor to see what could be done to advance research. The need for providing more accommodation was fully realized and schemes were in hand or in contemplation. Loans sanctioned last year for purposes of the Lunacy and Mental Treatment Acts were over £2,000,000 as compared with £1,700,000 in 1935-6. One of the best signs in connexion with the treatment of mental disease was a steady increase in the flow of voluntary patients. More than 25,000 patients were admitted last year to public mental hospitals, and of these nearly 27 per cent. were voluntary admissions. A larger number of people were seeking early treatment and had confidence in the institution. Out-patient clinics now totalled 165. To take over country houses for mental treatment purposes as suggested by Mrs. Tate would not be economic. It had been tried and found expensive. The importance of physical illness as a causal factor in mental disorder was widely recognized. Under the mental treatment rules the medical superintendent of an institution was required to send to the Board of Control a statement of the mental and bodily health and condition of the patient within seven days of the patient's admission.

The discussion was adjourned.

Pensions of Local Government Officers

The Local Government Superannuation Bill came before a standing committee of the House of Commons on June 22.

On Clause 5 (Power to admit employees to statutory undertakings) Captain ELLISTON moved to add a proviso which enabled a local authority operating the Midwives Act, in arrangement with a voluntary organization employing whole-time midwives, to admit such midwives to the benefits of the authority's superannuation scheme by agreement in the same way as employees of statutory undertakings could be admitted. Under such an agreement the employing organization would be required to make contributions to the funds in addition to the midwife's own contribution, and this would be taken into account in fixing the financial assistance given by the authority to the voluntary organization. The justification for the amendment was that midwives did on behalf of the local authority the same work that was done in other cases by municipal midwives. The committee agreed to the amendment, and Clause 5 was added to the Bill.

On Clause 6 (Contributions) Sir TERENCE O'CONNOR moved an amendment to provide that persons unable to discharge their duties in consequence of incapacity, whether transferred to another post or not, should be enabled to make their old contributions at their own expense in order to maintain the pensionable position as though they had not suffered a decline in health. He said that as the clause stood that right was restricted to people who were transferred from one post to another. The amendment was accepted, and the clause as amended was approved.

QUALIFYING PERIOD OF SERVICE

On Clause 8 (Eligibility for superannuation allowance and scale of allowances) Mr. GRANT-FERRIS moved to leave out "40" and to insert "30." He said his object was to press the advisability of altering the retiring age from 65 to 60. The non-professional employee started work under the local authority at the age of 20 or even younger, and thus was able to complete forty years of service and retire at the age of 60. The professional man could not start before he was 25, and thus was unable to retire until 65. A man should have the chance of getting out at 60 and securing some other congenial employment. In justice to doctors, engineers, veterinary

surgeons, and so forth, this opportunity of retiring at the age of 60 with pensions commensurate with their years of service ought to be allowed.

Sir KINGSLEY WOOD said Mr. Grant-Ferris wished to replace the period of forty years' service by one of thirty years. The committee that considered this matter made no such recommendation, and forty years was the limit for the purpose of the Poor Law Officers Act. In one or two cases, for which there was good reason, the qualifying limit was twenty years. There was an earlier retiring age under the Asylum Officers Act because of the arduous character of the work which male nurses in a mental hospital service were called upon to perform, and midwives and health visitors could qualify for pension after thirty years, again owing to the arduous character of their duties. No such conditions applied to the ordinary work of the ordinary local government employee. Forty years was the limit for the Civil Service. Sir Kingsley added that he could not accept the suggestion, as it would affect the stability and security of the superannuation funds. Mr. Grant-Ferris withdrew his amendment.

On Clause 12 (Reckoning of contributory and non-contributory service, and service of persons indirectly employed) Captain ELLISTON moved to insert the following:

> "In computing the amount of superannuation allowance payable under this Act, a local authority may, in consideration of peculiar professional qualifications or of special circumstances, with the consent of the Ministry of Health, add a number of years not exceeding ten to the number of years which the officer to receive the allowance has actually served in the aggregate.

He said the amendment expressed the feeling that added years should be allowable by a local authority in the case of its professional officers. These professional officers entered the service at a comparatively late age, and were commonly unable to achieve their full pensions. They entered at a salary level higher than that of non-professional officers, and one which climbed less speedily towards the maximum. Their contributions in proportion to the pension finally achieved were much higher than those of the non-professional workers. This applied especially to doctors.

Sir TERENCE O'CONNOR said he could not recommend the committee to adopt the amendment or to permit the principle to be established in the Bill The principle of added years had been condemned by the Royal Commission on the Civil Service, and had been abolished in the Civil Service since 1914. The amendment was withdrawn and the clause ordered to stand as part of the Bill.

Sir Terence O'Connor moved an amendment to Clause 16 (Midwives and health visitors). He said the clause as it stood gave effectual recommendation that the retiring age for female workers, midwives, and health visitors should be 65. Under this arrangement these women who had to go through a period of training beforehand could not complete forty years' service and earn the maximum pension if they had to retire at 60. The amendment would enable local authorities to grant compensatory allowances to nurses, midwives, and health visitors in their service as contributory employees even if they had not completed forty years' service on reaching the age of 60. These allowances would be on a scale to bring the pension at an earlier age up to that received if the women had been permitted to serve to the full age of 65. Any such addition to the pension earned would not be made from the pension fund, but would be voted out of the rates of the local authority. The amendment was approved, and Clause 16 as amended ordered to stand part of the Bill.

When discussion of the Bill was resumed on June 24 Sir KINGSLEY WOOD explained that the object of a proposed new subsection to Clause 26 was to empower local authorities to include in the scheme which they had to submit under that clause a provision whereby they could, if they wished, continue to require employees or prospective employees to pass a medical examination before coming into the superannuation scheme. The amendment was accepted and the clause approved.

"TEMPORARY" SERVICE

The Minister also brought forward a new clause dealing with whole-time officers appointed in a temporary capacity. He said he must have regard to the position of people who entered the local government service in a temporary capacity but remained for several years, and at the end of that time were in a position difficult to distinguish from those who had been placed on the permanent staff. The effect of the clause was that a local authority might in the case of any officer expressly engaged in a temporary capacity for the period of not more than two years determine that he should not be a contributory employee. At the end of two years' local government service, continuous or not, such an officer would automatically become a contributory employee whether he remained with the same authority or transferred within twelve months to another. In the latter case the authority by whom he was originally employed had to pay to the authority to which he went a prescribed transfer value. The clause was read a second time and added to the Bill.

Captain ELLISTON appealed to the Minister to provide interchangeability between the Federated Superannuation Scheme of the voluntary hospitals and the superannuation scheme under the Bill. Such a provision would promote interchange of personnel between the voluntary and the municipal hospitals, and would enhance the quality of hospital work all over the country. The matter was of special importance to nurses. Sir KINGSLEY WOOD regretted that there were almost insuperable difficulties of a financial and actuarial character which prevented reciprocal arrangements of the kind indicated.

The Bill as amended was reported to the House.

Public Exhibition of Animal Experiment Films

A Standing Committee of the House of Commons on June 23 considered the Cinematograph Films (Animals) Bill. The object of the Bill is to prohibit the public exhibition of films in the production of which suffering is caused to animals, or any films which depict the suffering of animals brought about by any means, either natural or artificial.

Sir ROBERT GOWLER moved an amendment providing that a cinematograph film shall be deemed to be exhibited to the public when, and only when, it is exhibited in a place to which for the time being members of the general public have access, whether on payment of money or otherwise, and the expression "public exhibition" to be construed accordingly. He said that the Bill would only affect the public exhibition of films, and it had been amended for that reason. It was represented to him and to the other promoters of the Bill by members of the medical profession that to-day a number of films showing demonstrations—he would not say experiments—on animals were taken and were used for the purpose of exhibitions to medical students and also to students in universities. Whatever the views of members of the committee might be on vivisection they would all agree that it was much better that use should be made of cinematograph films for this purpose than that the actual animals should be used for demonstrating. For that reason principally the promoters accepted the suggestion put forward by members of the medical and scholastic professions in this country that the Bill should be limited to public exhibitions of films. From inquiries he was satisfied that very few films were exhibited privately in this country. The great desire in passing this legislation was to discourage people abroad from making films by means which involved cruelty to animals.

Mr. RADFORD said that as one who did not like experiments on animals he thought that the amendment would tend to reduce the number of such experiments. If they could be reproduced on the film for the benefit of students there would not be the necessity for performing so many of them.

The amendment was agreed to and the Bill passed through committee.

Health Insurance of Juveniles

The text of the National Health Insurance (Juvenile Contributors and Young Persons) Bill, introduced by Sir Kingsley Wood, has been issued. An explanatory memorandum says the purpose of the Bill is to provide medical benefit under the National Health Insurance Act to boys and girls who, on

leaving school, become employed before reaching the age of 16, and thus to bridge the gap in medical supervision which at present exists between the school medical service and the commencement of full insurance under the National Health Insurance Act. The Bill accordingly provides that any boy or girl who, after reaching school-leaving age but before the age of 16, becomes employed within the meaning of the National Health Insurance Act, shall immediately become entitled as a "juvenile contributor" to medical benefit as though he were an insured person, and that whether or not he remains continuously employed he shall continue to be so entitled until the end of the half-year in which he attains the age of 16½, or until he becomes entitled to the benefit as a fully insured person by reason of employment after the age of 16, whichever first occurs.

FINANCIAL PROVISIONS

The contributions to be paid are 4d. a week, divided equally between the juvenile contributor and the employer. The cost of medical benefit and the cost of adminstration will be defrayed in the same manner as benefits under the principal Act—that is, as to six-sevenths (boys) and four-fifths (girls) out of the contributions, and as to the balance out of moneys provided by Parliament. The charge for medical benefit, including the supply of medicines and administration by insurance committees, will be on the same basis as for ordinary insured persons—namely, a sum not exceeding 13s. per head per annum—and provision will also be made for an allowance to approved societies for their work in the issue and collection of contribution cards, etc.

It is estimated that the number of juvenile contributors at the outset of the scheme will be about a million. Owing to the increase in the number of children remaining at school until the age of 15 after September, 1939, and the decrease in the number of births in the last fifteen years, the number of juvenile contributors will diminish in the next few years, and it is probable that by 1943 the number will not exceed 750,000.

SCHOOL MEDICAL RECORDS

The Bill provides that it shall be the duty of education authorities to make arrangements for their officers to furnish in confidence, on the application of an insurance medical practitioner, such particulars of the school medical record, either of a juvenile contributor or of any insured person under the age of 18, as the practitioner may require to assist him in the treatment and medical supervision of the young person.

In the Schedule to the Bill the appropriate provisions of the principal Act are applied, with or without modification, to juvenile contributors in order that the machinery and procedure of the main scheme may be utilized for this new class of contributor. Clause 7 provides in the usual form for the application of the provisions of the Bill to Northern Ireland under parallel legislation passed by the Parliament of that country. The Act is to come into operation from January 1, 1938, but contributions are only to be payable from the following Monday (January 3).

National Defence Contribution.—On June 21 the House of Commons approved a resolution authorizing a National Defence Contribution for five years at an annual rate of 5 per cent. on the profits for any trade or business. Sir JOHN SIMON, explaining why professions would be excluded, said: "Take two highly skilled medical men. One is a medical officer of health and the other is carrying on the private practice of a doctor—he is a doctor in the West End. He is taxed no doubt on his profession. His colleague in medicine who holds a public office is not taxed on the grounds of his profession at all, but is taxed as the holder of an office or as one engaged in an employment. If indeed we were to widen the scope of the tax in the way sometimes suggested we should find it extremely difficult to know where to stop. Why should you apply it to a West End doctor and not apply it to a medical officer of health?

MR. R. C. MORRISON: Does the right hon. Gentleman know a medical officer of health receiving over £2,000 a year?

SIR J. SIMON: It is easy to give an example of men who are professional but none the less are employed at high salaries.

Medical News

The ninety-sixth annual meeting of the Royal Medico-Psychological Association will be held at the County Buildings, Ayr, on July 7, 8, and 9. The in-coming president, Dr. Douglas McRae, will deliver his presidential address entitled "Some Observations on the Care of the Insane" at 2 p.m. on Wednesday, July 7, and the annual dinner will be held in the County Hall at 8 p.m. the same day. The subject for discussion at the meeting is "The Circulatory System and the Psychoses."

A meeting of the Society for the Study of Inebriety will be held at 11, Chandos Street, Cavendish Square, W., on Tuesday, July 13, at 4 p.m., when Mrs. Lilias M. Blackett Jeffries, M.D., will open a discussion on "Marriage in Relation to Alcohol and Drug Addiction."

The eleventh International Congress of Psychology, which was to have taken place at Madrid last September, will be held at the Sorbonne, Paris, from July 25 to 28, immediately before the ninth Congress of Philosophy. Further information can be obtained from M. I. Meyerson, Laboratoire de Psychologie, La Sorbonne, Paris, 5e.

The first International Congress of Infantile Psychiatry will be held in Paris from July 27 to August 1. Further information can be obtained from the treasurer, M. Gimbert, 11, Rue Duroc, Paris 7e.

The Royal Society of Tropical Medicine and Hygiene has awarded the Chalmers memorial gold medal for tropical research to Professor R. M. Gordon of Sierra Leone, and the presentation was made at the annual general meeting on June 17. The medal was founded by Mrs. Chalmers in memory of her husband, the late Dr. Albert J. Chalmers. It is awarded every two years in recognition of research of outstanding merit contributing to the knowledge of tropical medicine or tropical hygiene. The recipient must be under 45 years of age at the time of the award.

The trustees of the Lady Tata Memorial Fund announce that, on the recommendation of the Scientific Advisory Committee, they have made the following awards of grants and scholarships for research in blood diseases, with special reference to leukaemia, in the academic year beginning on October 1. Grants for research expenses or for scientific assistance: Dr. Julius Engelbreth-Holm (Copenhagen), Professor Dr. Karl Jármai (Budapest), Professor James McIntosh (London), Professor agrégé Dr. Charles Oberling (Paris), Professor Eugene Opie and Dr. Jacob Furth (New York), Dr. Georg Weitzmann (Leipzig), Dr. Lucy Wills (London). Scholarships: Dr. Jörgen Bichel (Aarhus, Denmark), Dr. Edoardo Storti (Pavia, Italy).

Lieut.-Colonel J. H. Yolland, C.B.E., has been appointed a vice-president of the Kent Branch of the British Red Cross Society.

Sir Harry Lindsay, K.C.I.E., Director of the Imperial Institute, has accepted nomination as President of the Association of Special Libraries and Information Bureaux (ASLIB) for the year 1937–8. The Association will hold its fourteenth annual conference at Gonville and Caius College, Cambridge, during the week-end beginning September 24. Particulars may be obtained from the Secretary of the Association, 31, Museum Street, W.C.1.

Miss Ethel Benwell has retired from the service of the British Medical Association after completing thirty-seven years' work in the Editorial Department. Miss Benwell joined the staff of the *British Medical Journal* on May 28, 1900, and on June 30, 1937, presentations were made to her by the Editor and his immediate colleagues, and by other fellow workers at Tavistock Square.

The fourth Congress of the Medical Women's International Association—of which the Queen is Patron—takes place in Edinburgh from July 13 to 18. The inaugural meeting will be held at 2.30 on Wednesday, July 14, in the McEwan Hall, University of Edinburgh. The speakers include Dr. Sundquist (president of the M.W.I.A.), Sir Thomas Holland (Vice-Chancellor of the University of Edinburgh), Sir Norman Walker, Sir William McKechnie, and representative medical women from different countries. Intending members who have not yet enrolled should apply to the local congress secretary, 2, Chester Street, Edinburgh, for any information.

July 7 marks the centenary of the birth of Sir Morell Mackenzie, the eminent Victorian laryngologist whose textbook on diseases of the throat and nose was for a long time a standard work on the subject. His obituary notice was published in the *British Medical Journal*, 1892, **1**, 363.

Two cases of yellow fever, which has hitherto been unknown in Asia, have recently been reported in Hong Kong.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES are
EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the B.M.A. Scottish Office is 7, Drumsheugh Garden[illegible]grams: *Associate, Edinburgh*; telephone [illegible] and of the Office of the Irish Free State [illegible].A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone 62550 Dublin).

QUERIES AND ANSWERS

Sun Sensitivity

"F. L." would be glad of suggestions for treating a case of sensitivity to sunlight. The lady concerned has only to go out in the sun for a short time to occasion a blotchy, erythematous, irritable rash of the parts exposed, which lasts for days. Once, when she had an exposure to "artificial sunlight," she had a reaction sufficient to blister. The persistent rash responded immediately to injections of Martindale's "peptone," but exposure to sun still causes some recurrence, although less severe.

Cancrum Oris

Dr. HOPE TRANT (N. Rhodesia) writes: Medical practitioners in Africa must see many cases of cancrum oris amongst native children. I should be glad to have their opinion on how best to treat it. Curettage, in my experience, is of no value.

Splitting Finger-nails

"E. P.," in reply to "Stumped" (*Journal*, May 29, p. 1144), writes: I find that splitting of the finger-nails is often due to the use of liquid nail polish and polish remover. It can be alleviated by rubbing a little oil of almonds on the nails and cuticle at bed-time.

The Aftermath of Sympathectomy

Mr. J. B. OLDHAM, F.R.C.S. (Liverpool), in reply to "Perturbed" (*Journal*, June 19, p. 1295), writes: I feel sure that the reason why "Perturbed" has seen no allusion in the literature to derangement of the bowels or bladder is that lumbar sympathectomy never has any such ill effects. My own experience extends over ten years and covers nearly a hundred cases, all of which have been carefully followed up. No patient has ever had any bladder complications. Those whose bowel function was normal before operation have noticed no change afterwards, while those who were constipated beforehand found that their constipation was either cured or greatly improved. Two of my patients operated on nine years ago have since borne children, so that there can be no fear of the operation interfering with conception or labour. On the other hand, in the male lumbar sympathectomy results in sterility, as the power of ejaculation is lost. I have found that only in a very few cases of Raynaud's disease are the feet affected severely enough to justify operation, but in those few cases in which operation was done the patients have considered the result a complete and lasting cure. Like all other surgeons, however, I have been disappointed with post-ganglionic sympathectomy in the upper limbs. I am convinced that the extraperitoneal approach to the sympathetic chain is preferable to Adson's transperitoneal method, even when both sides have to be operated on. The operation can be done by a simple muscle-splitting incision in under twenty minutes, and affects the patient so little that he can be up and walking in less than a week.

Professor E. D. TELFORD (Manchester) writes: I have during the last six years performed lumbar sympathectomy in more than 200 patients. The operation is a cord ganglionectomy in which the lumbar sympathetic chain is excised over a length corresponding to the bodies of the second, third, and fourth lumbar vertebrae. These patients have been examined repeatedly since the operation and in no single case, male or female, has any bladder, bowel, or sexual disability been evident. It is true that certain disabilities, mainly sexual, are likely to follow resection of the presacral nerve, but this nerve would never be divided in the treatment of vascular disorders of the lower limb. In cases of Raynaud's phenomenon in the lower extremity my experience is that lumbar-cord ganglionectomy results in a cure which is complete, and, I believe, permanent. It is otherwise with the upper limb. My present view is that excision of the stellate ganglion should not be done: the operation is followed by relapse. The pre-ganglionic section which I designed in February, 1935, and have since carried out in some twenty patients has given excellent results in all cases, but further time must elapse before one can say with confidence that these results will last.

Income Tax

Structural Expenditure

"X. Y. Z." recently enlarged his house, including parts used professionally, and had central heating installed. Can he deduct a proportion of such expenditure in computing his income tax liability?

*** No—the expenditure represented capital outlay and not current professional costs. It might, however, be possible to obtain some allowance by way of depreciation, say, at 5 per cent. per annum, for that part of the outlay which relates to the heating of the professional rooms.

LETTERS, NOTES, ETC.

Medical Golf

The summer meeting of the Medical Golfing Society was held at Sunningdale on June 24, when some seventy members competed over a course which was in perfect condition. Several competitions took place, and the following are the results. *Lancet* Cup: T. P. Kolesar. Henry Morris Cup: H. L. Glyn-Hughes. Gordon Watson Cup: J. Grace. Class I: first, H. Lamplough; second, T. P. Kolesar; last nine, V. E. Negus. Class II: first, H. L. Glyn Hughes; second, L. Hartley; last nine, R. Lindsay Rea. Foursomes: (1) Michael Smyth and J. McGrath; (2) Jocelyn Swan and S. Wyard. Knock-out Tournament: winner, N. L. Eckhoff.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

1 Physiological and Pathological Sleep

L. HESS (*Klin. Wschr.*, May 1, 1937, p. 625) draws attention to the fact that it is not always possible to differentiate between natural sleep and pathological states resembling sleep—for example, *hypnosis, narcolepsy, coma* following poisoning, diabetic coma, uraemia, or shock. During physiological sleep the eyelids are completely closed, the cornea is reddened, the pupils are miotic, and the eyeball is turned upward and usually inward. On awakening there is temporary incoordination of movement of the eyes. In pathological states resembling sleep there is no miosis of the pupil, *except in morphine poisoning*, and the eyeballs are not turned upward and inward. In physiological sleep the face is slightly reddened, breathing is fairly regular but slow, the pulse rate is slow, and the blood pressure lowered; there is complete muscular relaxation, but anaesthesia is incomplete. On awakening dreams may be remembered, but the individual feels refreshed, and in many cases sleep may be terminated voluntarily. In pathological states resembling sleep the face remains pale, the breathing is irregular, muscular relaxation is incomplete and may be interrupted by a clonic spasm of individual muscles, and it may be impossible to awaken the patient. On being roused he feels depressed and unrefreshed and may complain of headache. There is amnesia of the coma and the period immediately prior to it. Pathological states last longer than physiological sleep, and cannot be terminated voluntarily. Hess believes that a sleep centre exists in the mesencephalon in front of the nucleus of the oculomotor nerve. Inhibition of this centre and of nerve paths to the cortex and optic thalamus results in physiological sleep. Pathological inhibition in this area results in states similar to sleep, but whereas in physiological sleep inhibition is reversible, it is not so in pathological conditions.

2 Ascorbic Acid

K. U. TOVERUD (*Norsk Mag. Laegevidensk.*, May, 1937, p. 441) has investigated the conditions under which ascorbic acid, vitamin C, is excreted and retained in the human body. This research was stimulated by the observations of Harris and Ray, who found that the daily excretion of ascorbic acid is comparatively low in persons whose intake of vitamin C has been short for some time. They also found that such persons did not show a marked increase of this vitamin in the urine after a large test dose of it. They therefore suggested that the actual amount found in the urine might be an index to the degree of vitamin C deficiency from which the tested person was suffering. Toverud's two main objects were to ascertain the amount of daily excretion of ascorbic acid under normal conditions, and the way in which the normal organism on a good dietary reacted to a large single dose. The author gave orange juice as a source of vitamin C. He found that eight normal women living on a diet containing a little fresh fruit and vegetables, at least half a litre of milk, an egg, bread, and meat or fish excreted on the average 35 mg. of ascorbic acid daily. When half a litre of orange juice, containing 250 mg. of ascorbic acid, was added to the diet 50 per cent. or more of this acid was excreted in the urine during the first twenty-four hours. When ten normal children living on an ordinary mixed diet were tested with 200 to 300 c.cm. of orange juice, not more than 30 per cent. of the ascorbic acid thus given was excreted in the urine. Twelve pregnant women and a certain number of lactating women were tested in the same way, and it was found that their excretion after a test dose was remarkably low. It would appear, therefore, that the requirements of ascorbic acid are greater in childhood than in adult life, still greater in pregnancy, and greatest of all in lactating women.

3 Tuberculin Reactions and Radiographs

O. SCHEEL (*Nord. med. Tidskr.*, May 15, 1937, p. 761) draws attention to the difficulty of classifying the reactions to the Pirquet and Mantoux tests when they are neither definitely positive nor negative, and he admits that the decision is apt to be arbitrary. He has compared tuberculin tests and radiological findings in a series of 1,697 students, with no previous record of tuberculosis, and who had not been vaccinated with B.C.G. They were classified as tuberculin-negative or positive, but among the 851 tuberculin-negative as well as among the 846 tuberculin-positive were several cases in which the reaction was doubtful. In each of the two main groups there were therefore several subgroups. The radiological findings were classified according to whether (1) the abnormalities were confined to the pleurae, (2) they consisted of non-calcified shadows in the lungs with or without pleural changes, or (3) of calcified patches in lungs or glands with or without pleural changes and other shadows. It was found that changes limited to the pleura were as frequent among the tuberculin-negative as among the tuberculin-positive students, the incidence of such changes ranging from 3.1 to 6.5 per cent. in the different subgroups. The author interprets this as indicative of the non-tuberculous character of such pleural changes when unaccompanied by other radiological findings. Non-calcified lung shadows were much more frequent among the tuberculin-positive than among the tuberculin-negative, and were found in from 0 to 6.9 per cent. in the different subgroups of the tuberculin-positive group, but only in from 0 to 1.6 per cent. in the different subgroups of the tuberculin-negative group. The radiological changes, which included calcification, were about twenty times as frequent among the positive as they were among the negative reactors. The author proposes that a border-zone reaction between a positive and a negative Pirquet test should be regarded as one in which an induration between 2 and 3 mm. wide appears forty-eight hours after the first injection. This refers only to infection with the human type of tubercle bacillus.

Surgery

4 Non-specific Chronic Synovitis of the Knee

C. BARTHELS and H. BERNAU (*Zbl. Chir.*, April 3, 1937, p. 778) find few references in the literature to the late stages of simple chronic synovitis of the knee. The condition tends to affect young persons, and to occur ultimately in both knees. There is usually a slight rise of temperature. Pain is slight and depends on the amount of exudate. The authors were able to examine thirty-two cases two to twenty years after the occurrence of the condition. In all cases the diagnosis was certain, as it had been made by biopsy and culture of synovial fluid. In twenty-eight cases only one knee was affected; in eighteen the temperature was slightly raised; and the effusion persisted usually for from ten to twenty weeks. Some form of treatment had been carried out in all the cases, including puncture of the joint, injection of iodoform and glycerin, immobilization with plaster-of-Paris, and *x*-ray and short-wave therapy. One-third of the

patients complained of pain on movement to a greater or lesser extent. *X* rays showed complete cure in one-third of the cases; in another one-third there were signs of early arthritis deformans; and in the others there were grave changes in the knee-joint. The condition began in three cases from the ages of 1 to 10, in nineteen from 10 to 20, in seven from 20 to 30, and in three from 30 to 40. The authors found that as a rule when the condition occurred before puberty complete cure resulted. Even in these cases, however, when the effusion remained over a long period or recurred frequently, changes of the arthritis deformans type were seen. In nineteen cases arising after the age of 16 only four were completely cured. The authors believe that the prognosis depends chiefly on the time for which the inflammatory process persists and on the number of recurrences. In cured cases the effusion lasted usually from three to ten weeks, and in only one case was there a recurrence; in the worst cases the effusion had been present for one year, and in two-thirds there were recurrences. In view of these facts they advocate the making of a small window in the capsule to lessen the duration of the effusion.

5 Cryptorchism

H. BJERRE (*Ugeskr. Laeg.*, May 13, 1937, p. 513) has collected 196 cases of undescended testicle, operated on in Copenhagen between 1900 and 1930, and has found that in 58 per cent. good results were achieved, whereas in 32 per cent. the results were disappointing, and in 10 per cent. the operations were followed by atrophy of the testicles. His control material consisted of 188 cases, in which no operative treatment was attempted. In 63 per cent. the testicles descended into the scrotum unaided, and in almost every case in which this happened the patients had not reached the age of 15. The similarity of the results in these two groups suggests that the operative successes in the former group are precisely those which could have been achieved by a policy of masterly inactivity. These observations contraindicate operative treatment in childhood unless the surgeon has to treat a hernia, or there are bouts of pain indicative of torsion or incarceration of the testicle. If, however, the cryptorchism persists until puberty an operation is indicated, for it will probably have to be undertaken sooner or later on account of complications which grow more frequent with advancing age. At the beginning of puberty the lodging of the testicle in the scrotum offers the only possibility of developing a functionally normal organ, and as its atrophy, if still undescended, begins about the age of 16 it is as well to operate before then. A classification of the patients by age at the time of operation showed that between 0 and 15 the prognosis was identical, whereas after puberty the proportion of successes was halved. The hormone treatment of undescended testicle is, in the author's opinion, in too early and experimental a stage to warrant a considered opinion on its merits.

6 Localized Osteitis Fibrosa

S. KOIDE (*Jap. J. med. Sci. IX Surg.*, March, 1937, p. 27) found a history of early and appreciable trauma in 30 per cent. of cases of localized osteitis fibrosa. In no case was there evidence of a parathyroid tumour, and the calcium content of the blood was approximately normal. The radiographs showed a localized well-delimited bone destruction. Occasionally the tumour formed a localized cystic swelling. Small foci usually destroyed the inner surface of the cortical bone only; larger foci might cause excessive thinning of cortical bone, though the outer surface usually remained smooth. There were no changes in the surrounding soft tissues. There was occasionally spontaneous fracture, but never bony deformity. It was impossible to decide whether the tumour originated in the epiphysis or diaphysis. In no case was there sarcomatous degeneration or metastatic dissemination of the tumour. Infiltration with xanthomatous froth cells was observed in 70 per cent. of cases. These xanthomatous cells belonged to the macrophages and were intimately connected with the cholesterin esters. The neoplastic tissues were generally rich in lipoids, and the tumour cells as well as the giant cells took part in the phagocytosis of the lipoids. The giant cells did not contain any ferrous blood pigments, which pigments as well as lipoids were mainly found in the fusiform histocytes. The author advises conservative surgical treatment even in advanced cases. The tumours should be curetted and filled with paraffin, and resection should only be done as a last resort.

Therapeutics

7 Mandelic Acid in Urinary Infections

E. SCHNOHR and C. JOHANSEN (*Hospitalstidende*, April 27, 1937, p. 453) have treated in the course of a year thirty cases of pyelitis and cystitis with mandelic acid. In all but four cases the diagnosis of pyelitis was verified by cystoscopy and catheterization of the ureters. The mandelic acid was given in the form of sodium amygdalate six times a day. In twenty-three cases the urine was rendered sterile in from three to thirty days. Among the seven failures in this respect were two patients who could not take the mandelic acid for more than a day because it made one of them vomit and increased the dysuria of the other. In a third case the patient left hospital after six days for private reasons. During the treatment there was in most cases a rapid and striking clinical improvement. The author does not recommend this treatment until a few days in bed have reduced the toxic phenomena and lowered the temperature, for he believes that during the acute stage of pyelitis the renal parenchyma is involved, and might suffer if it had to excrete a highly acid urine. While several other observers have found casts and albumin in the urine under mandelic acid and ammonium chloride treatment, the author never has, and he traces this immunity to the precaution of keeping the patient in bed for a few days. He considers this treatment superior to all others in dealing with infections of the urinary tract, and in a postscript to his paper he states that in eight cases he has achieved the same therapeutic successes with a new preparation of mandelic acid combined with a calcium salt, which is tasteless and gives rise only to insignificant digestive disturbances.

8 Transcerebral Bee-venom Ionophoresis

P. CERANKE, G. SCHEID, and A. STERN (*Med. Klinik*, April 30, 1937, p. 609) have obtained encouraging results with transcerebral bee-venom ionophoresis in cases of high blood pressure. The bee venom is rubbed into the skin of the forehead. The positive electrode, made of a sheet of lead measuring 14 by 6 cm. and padded with a folded towel about 5 cm. thick, is applied to the forehead. A similar electrode is applied to the nape of the neck and is connected to the negative pole. A galvanic current of 2 to 5 milliamperes is applied for fifteen minutes, and the treatment is given daily. The skin under the electrode reddens and may even blister. The treatment proved quite harmless and the therapeutic results were consistently good.

9 Novalgin in Biliary Colic

G. V. BEIN (*Münch. med. Wschr.*, April 23, 1937, p. 651) recommends intravenous injections of novalgin for the relief of biliary colic. He injects 4 to 5 c.cm. of a 50 per cent. solution of novalgin even in debilitated patients. The pain disappears usually after about five minutes. Of the 124 cases treated only 7 per cent. failed

to respond to this medication. In very severe attacks the author recommends a simultaneous injection of 2 c.cm. of novatropin. According to him this medication is preferable to morphine, as it does not daze the patient and there is no danger of drug addiction in chronic cases.

Anaesthesia

10 High Lumbar Anaesthesia

R. FINALY (*Nederl. Tijdschr. Geneesk.*, April 24, 1937, p. 1815) states that until recently lumbar anaesthesia was used only in operations below the umbilicus. Within the last few years, however, Howard Jones's solution of hypobarium and percaine has been employed according to Sebrechts's fractional method for supra-umbilical operations. Since 1934 Finaly has used this method in 103 cases. In 68 per cent. of these cases the anaesthesia reached above the umbilicus in operations involving the stomach, colon, liver, and gall-bladder, and the same applied to 29 per cent. of gynaecological cases. Finaly comes to the conclusion that Sebrechts's method should not be confined to operations in the epigastric region, and that it is superior to all other methods in its safety and in the duration of the anaesthesia.

11 General Spinal Anaesthesia

E. G. JAUREGUI (*Cirurg. Ciruj.*, March, 1937, p. 135) gives a detailed description of Koster's method of general spinal anaesthesia, laying special emphasis on the size of the needle and the rate of intrathecal injection of the fluid. After dealing with the prevention of complications caused by the anaesthetic, such as headache and paralysis of the bladder, he dismisses the view that anaesthetic can be conveyed to the bulbar centres. He alludes to the experiments of Koster, showing that strong solutions of novocain applied to the upper part of the spinal cord, while producing complete anaesthesia, do not affect the cardiac or respiratory rhythm. Nervous conductivity under the influence of the anaesthesia is at first preserved, but afterwards disappears suddenly without any period of excitability.

12 Analgesia in Labour

A. D. GLADISH and R. O. ELDER (*Sem. méd.*, B. Aires., April 1, 1937, p. 932), who record ten illustrative cases in women aged from 20 to 29, employed nitrous oxide, ethylene, and cyclopropane as analgesics in labour, and have come to the conclusion that these agents, unlike chloroform and ether, have no influence on the uterine contractions. In some of the cases the uterine relaxation between the contractions was greater with the analgesic than without it. In two of the cases treated with cyclopropane uterine inertia occurred accompanied by haemorrhage. The authors propose to study further this rare condition in order to determine whether or not their results agree with those of American writers who have not observed this complication.

13 General Anaesthesia in Tonsillectomy

T. BETSHOLTZ (*Hygiea*, Stockh., May 15, 1937, p. 319) reports from a hospital in Lund, Sweden, follow-up studies of 1,405 persons on whom tonsillectomy had been performed in the five-year period 1930–5. These studies were prompted by the case of a woman, aged 38, on whom tonsillectomy had been performed under intratracheal nitrous oxide anaesthesia for the relief of recurrent attacks of sore throat. Shortly after the operation she developed a pulmonary abscess from which she ultimately recovered under conservative treatment. Wondering if similar or other ill effects had escaped his notice among the 1,726 patients operated on, the author addressed a questionary to them, and in 1,405 cases he received answers. Though no other case of pulmonary abscess had to be recorded, there were three cases in which pleurisy and two cases in which bronchitis occurred after the tonsillectomy under nitrous oxide anaesthesia. As bronchitis is no uncommon event in the highly infectious atmosphere of a throat and ear hospital, these two cases cannot necessarily be regarded as due to the operation or anaesthetic; and there remain the one case of lung abscess and the three cases of pleurisy for which the operation or the anaesthetic, or both, might be held responsible. This represents a risk of 0.3 per cent., and as it is only possibly, not certainly, connected with the general anaesthetic given, the author does not propose to abandon the nitrous oxide anaesthesia, which he has employed for tonsillectomy during the five-year period under review. He is confirmed in this decision by the reflection that the risks of the above-mentioned complications cannot with certainty be eliminated by performing tonsillectomy under local anaesthesia.

14 Cyclopropane Anaesthesia

H. R. GRIFFITH (*Canad. med. Ass. J.*, May, 1937, p. 496) has personally administered cyclopropane more than 2,500 times since 1933 with increasing satisfaction. He considers that it most nearly approaches the ideal anaesthetic agent, and that it can be used for almost every type of patient and for all kinds of operation. Its outstanding advantages are the rapid and easy induction, complete oxygenation, good relaxation, and prompt recovery with little after-effects. As his experience has increased he has used ether less frequently, and now hardly ever requires it, even for upper abdominal operations. The smoothness of the post-operative course is shown by a comparison of the last 100 cases of Caesarean section, done under cyclopropane, with the previous 100 cases, done mainly under ethylene and ether. In the latter there were twenty-four cases of severe distention, seven of which went on to paralytic ileus, whereas with cyclopropane there were only two cases of distension and none of ileus. It has also been used with success in 300 obstetrical deliveries. The author considers that the increase of capillary bleeding sometimes ascribed to cyclopropane is open to question, and that the explosion risk is no greater than when other inflammable agents, such as ether and ethylene, are used. The Waters carbon dioxide absorption technique which he adopted helps to reduce this risk.

15 Intravenous Pentothal Sodium

J. H. HUTTON and R. M. TOVELL (*Surg. Gynec. Obstet.*, May, 1937, p. 888) record 2,700 administrations of pentothal sodium for intravenous anaesthesia. They consider that it is the most effective short-acting barbiturate yet introduced, and that its rapid destruction in the body allows a degree of control by intermittent injection similar to that given by open ether. Except in minor cases they recommend preliminary sedation with 1½ grains of nembutal and 1/6 grain of morphine, to which may be added 1/150 grain of atropine if inhalation anaesthesia is to follow. The 5 per cent. solution is prepared before use, and should be clear, of greenish-yellow colour, and with a slight odour of sulphur. The average initial dose for adults is 4 c.cm. given in fifteen to twenty-five seconds, after which further injections of 1/2 to 1 c.cm. are made as required. There is seldom any tremor or movement during induction, and restlessness on recovery is rare. Since the drug is a powerful depressant the respiration must be carefully watched and the airway maintained, while the pulse rate and blood pressure should be frequently observed. It should only be used by experienced anaesthetists capable of dealing with emergencies. Pentothal may also be given for controlling convulsions caused by drugs, etc., and it may be used for prognosis in Raynaud's disease.

Obstetrics and Gynaecology

16 Length and Weight of Infants at Birth

F. A. WAHL (*Dtsch. med. Wschr.*, May 14, 1937, p. 769) reports his observations from the University Maternity Hospital in Cologne on 5,901 full-term infants born in the period 1932–5. Their average length at birth was 51.47 cm. and their average weight was 3,404 grammes. These figures are considerably in excess of those quoted as normal averages in the textbooks, and the author is inclined to associate this with an average duration of pregnancy of 284 to 285 days, an interval which is four to five days longer than that hitherto regarded as the average gestation period in Germany. Three of the authors he quotes give 50 cm. as the average length of a normal full-term infant at birth, and the average weight in grammes is 3,000, 3,200, and 3,000 to 3,300 respectively. An average, struck by fusing the figures of these three authors with those of two others, gives a length of 50 cm. and a weight of 3,250 grammes. The author puts the duration of pregnancy at 285 days after menstruation, 273 to 274 days after ovulation, and 270 days after conception. The corresponding number of days according to textbook reckonings are 280, 270, and 265 respectively. The author connects the changes in length and weight of infants at birth and in the duration of pregnancy with the improved circumstances under which the expectant mother lives in Germany at the present time, changes comparable with those in the average height and weight of adult human beings and in their expectation of life.

17 Actinic and Operative Sterilization

E. MOMIGLIANO (*Ann. Ostet. Ginec.*, March 31, 1937, p. 251) carried out investigations on rabbits which showed that sterilization by *x* rays produced a much slower and less intense involution of the uterus than did operative sterilization. In contrast to bilateral ovariotomy, irradiation of the ovaries did not interrupt the oestral phenomena, which continued for a relatively long period, although their rhythm was somewhat different from the normal. The maturation of the Graafian follicles continued even when the *x* rays had induced a general involution of the follicular apparatus, and even for some time after the ovary had become merely a mass of interstitial tissue. Momigliano concludes that the secretion of folliculin is not only due to the cells of the granulosa but also to the interstitial cells. The persistence of these cells after involution of the follicular apparatus accounts for the persistence of the internal secretion of the ovary after actinic sterilization, and thus explains the differences occurring not only locally but throughout the system after operative sterilization.

18 Expulsion of Foetus through Placenta Praevia

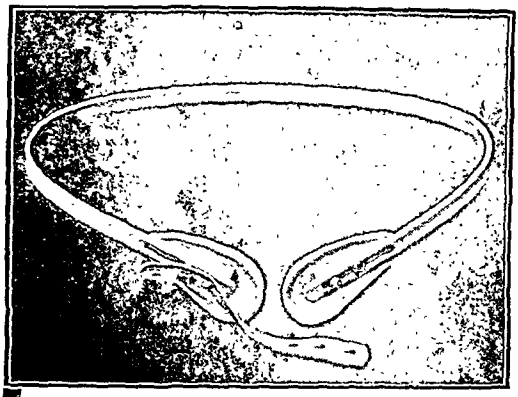
O. VIANA (*Rif. med.*, April 17, 1937, p. 563) records the case of a multipara, aged 41, who had previously undergone Caesarean section for placenta praevia and had come to term with her sixth pregnancy without any uterine haemorrhage. The foetus died, but was not expelled owing to adhesion of the os internum to a centrally placed placenta praevia. Labour was induced, and the foetus was delivered through the placenta without any haemorrhage. Subsequent recovery was uneventful.

19 Abnormalities of the Bony Pelvis

R. L. LIVCHINA (*Gynéc. et Obstét.*, April, 1937, p. 274) reviews 13,200 deliveries which took place at the Obstetric Clinic of the Medical Institute of Charkov. Fifteen per cent. of the women suffered from narrow pelvis, and in all these cases labour was managed on strictly conservative lines. Spontaneous delivery occurred in 91.5 per cent. with no maternal mortality, and with an infantile mortality of 2.8 per cent. In 8.5 per cent. surgical intervention was thought advisable. In these cases the maternal mortality was 0.6 per cent. and the infantile mortality 34.5 per cent. The average maternal mortality for the 13,200 cases was 0.05 per cent., the average infantile mortality 5.5 per cent. In cases of disproportion the author considers Caesarean section as the treatment of choice. Abdominal Caesarean section was carried out in only 0.25 per cent. of all cases, vaginal section in 8.25 per cent. The author concludes that spontaneous delivery should be aimed at in all these cases in preference to Caesarean section.

Pathology

20 Castration and Mammary Carcinoma



W. E. HERRELL (*Amer. J. Cancer*, April, 1937, p. 659) refers to recent animal experiments dealing with the incidence of mammary carcinoma in castrated mice. It was found that castration of female mice when under 6 months of age, in a strain in which the incidence of mammary carcinoma was high, led to a decrease in tumour formation. Castration between the fifteenth and twenty-second days of life prevented the occurrence of spontaneous adenocarcinoma of the breast altogether. Animal experiment establishes the part played by ovarian activity in the development of carcinoma. Its influence is specific, for oöphorectomy does not lead to resistance against other types of spontaneous malignant tumour. Studying the subject in the human female, Herrell reviewed 1,906 records in the Mayo Clinic of women operated on for mammary carcinoma, and 1,011 control records of women of 40 years and over without carcinoma of the breast. In all cases a history of oöphorectomy or castration by *x* rays or radium was sought for, and the time between the castrating procedure and the origin of the complaint determined. The author found that in 1,906 cases of mammary carcinoma twenty-eight patients (1.5 per cent.) had been previously castrated. In eight of these oöphorectomy had been performed within three years of the onset of the cancer. In the control series of 1,011 patients 15.4 per cent. had been oöphorectomized. Of eighty-five patients with a partial oöphorectomy fifteen required total extirpation of the ovaries at a later date. The author concludes that since the incidence of castration in the non-cancer group is ten times as great as that in the cancer group, the function of the ovaries in the production of mammary carcinoma may be as definite in human beings as it is in animals.

21 Cellular Diagnosis

F. WUHRMANN (*Münch. med. Wschr.*, May 28, 1937, p. 860) describes a special histological technique for the investigation of secretions and biopsies obtained by puncture in cases of neoplasm. The material is centrifuged and the sediment embedded in paraffin. The technique is described in detail. The diagnosis must be based on the examination of a conglomeration of cells and not of isolated ones. This applies equally to fresh specimens, however good the staining methods may be. The clusters of neoplastic cells can be distinguished from endothelial cells by their pale protoplasm after they have been stained with the usual haemalum-eosin. Endothelial cells may be found in exudates caused by neoplasm, but they are mainly typical of pleural exudates in cases of pulmonary infarcts, in peritoneal effusions, and in Laënnec's cirrhosis of the liver. They are usually absent in tuberculous effusions, but lymphocytic sediments suggest tuberculosis. The relative numbers of lymphocytes and leucocytes in the blood count vary according to the intensity of the inflammation, the leucocytes increasing as the inflammatory process becomes more pronounced.

SALTAIR SURGICAL SERVICE

Guarantee
"We guarantee to alter exchange or accept the return of any appliance without cost ordered by the Medical Profession, if not found suitable within fourteen days from date of supply."
Salt and Son Ltd.

SALT'S CELLULOID-COVERED TRUSS

WITH SOLID CELLULOID PAD

No matter how hot the weather, a patient wearing this Truss always feels comfortable. Light in weight but perfectly efficient, this celluloid-covered Truss has a lifetime that is more than twice as long as that of a leather-covered one. Even bathing may be indulged in quite safely, for the Truss can be easily dried afterwards. Practitioners are invited to write for descriptive catalogue, which contains convenient Measure/Order Forms.

BORWICK'S *Cold Water* LEMON BARLEY POWDER

A NEW AND UNIQUE DRINK, SPECIALLY RECOMMENDED FOR NURSING HOMES AND INSTITUTIONS

BECAUSE—IT IS MADE FROM PURE NATURAL BARLEY AND LEMONS AND CONTAINS NO ARTIFICIAL ESSENCE WHATSOEVER. *(Public Analyst's Report)*

Borwick's Cold Water Lemon Barley is made in a few seconds, needs no boiling, nor need anything be added except cold water. Refreshing, invigorating, and is guaranteed absolutely pure.

BORWICK'S COLD WATER LEMON BARLEY POWDER

In attractive tins: 10½d, 1/3 and 2/3. Larger sizes for Institutions. Stocked by leading Chemists and Stores.
Sample will be gladly sent on application to:
GEORGE BORWICK & SONS LTD., 1, Bunhill Row, London, E.C.1. (Established nearly a Century)

ECZEMA

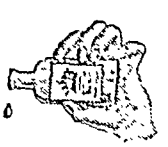
Relief and cure with Peat ointment.

Because eczema generally brings pain and itching, any local dressing should attempt soothing as well as healing. And this is the great virtue of Sphagnol peat ointment — that from its first touch, it gives coolness and comfort to tender skin.

Many doctors find Sphagnol so successful that they are prompted to write about it. Here is an extract from one of the letters we have received:

"Thank you for the ointment. I have tried it on an incipient case of local eczematous trouble and found it to give great relief and to arrest the manifestation." Signed (Dr.) R. L.

Test Sphagnol personally. On receipt of a postcard we shall be pleased to send you a sufficient supply.



Sphagnol

Peat Products (Sphagnol) Ltd., Dept. B. 210, 21, Bush Lane, London, E.C.4.

No time for Colds

The busy practitioner cannot allow a cold to impair his efficiency or infect his patients. Many medical men not only prescribe Vapex but use it regularly as a prophylactic. Most patients know the pleasant, refreshing odour and like to think that their doctor is taking precautions for their safety as well as his own.

'VARIBAN' ELASTIC PLASTER BANDAGE

"VARIBAN" BANDAGE constitutes a marked advance on the older methods of treating chronic ulceration of the leg. It is made from a specially woven selvedge material possessing highly elastic properties, and is impregnated with an antiseptic zinc oxide paste.

"VARIBAN" is self-adhesive and combines the principles of firm, equable pressure and support to the swollen leg, with the benefit of an occlusive dressing under which the ulcer is protected and is stimulated to healthy repair.

In promoting proper circulation, "VARIBAN" steadily reduces oedema. It provides protection to the granulations of the healing ulcer. In the majority of cases it is found that pain is either eliminated or greatly relieved from the first application. The necessity for ointments, lotions, etc., is obviated, while "VARIBAN" provides an ambulatory treatment which allows of full activity of the limbs with better results than those following rest in bed alone.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble, temporary patients, and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray room, an Ultra-Violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation Therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate, a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. *There is trout-fishing in the park.*

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts) croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton), who can be seen in London by appointment.

NORTHUMBERLAND HOUSE,

GREEN LANES, FINSBURY PARK, N.4.

A PRIVATE HOSPITAL for the treatment of mental and nervous illnesses. Conveniently situated and easy of access from all parts. Six acres of ground, highly situated, facing Finsbury Park. THE RESIDENTIAL TREATMENT OF ALCOHOLIC & DRUG ADDICTION

RENDLESHAM HALL

(Postal Address) — **WOODBRIDGE, SUFFOLK**

RENDLESHAM HALL—SOUTH VIEW

Rendlesham Hall, which is open to receive patients, is essentially a Sanatorium. Its daily life and routine are that of an ordinary comfortable holiday or health resort, or of a large country house. Each patient has all the privileges of a guest consistent with the prescribed medical treatment.

Rendlesham Hall has 45 bedrooms, and about 450 acres of gardens and park. It has also a private nine-hole golf course, tennis and croquet lawns, and bowling green.

Illustrated booklet giving particulars as to terms, etc., can be had on application to the

RESIDENT MEDICAL SUPERINTENDENT.

Telegrams and Telephone: WICKHAM MARKET 16. *(Toll Call from London.)*

Proprietors: The Norwood Sanatorium, Limited.

BETHLEM ROYAL HOSPITAL, for Nervous and Mental Disorders

Monks Orchard, Monks Orchard Road, Eden Park, Beckenham, Kent.

Reg. Tel. Address: Bethlem, Beckenham. *Station:* Eden Park (Southern Railway). *Telephone:* Springpark 1180-1181.

President: VISCOUNT WAKEFIELD OF HYTHE, G.C.V.O.
Treasurer: SIR LIONEL FAUDEL-PHILLIPS, Bart.
Physician-Supt.: J. G. PORTER-PHILLIPS, M.D., F.R.C.P.

This Registered Hospital is now situated at Monks Orchard, in some 250 acres of park, pleasure, and farm grounds.
Applications can be considered on behalf of patients of the educated classes in a presumably curable condition.
With a view to early treatment voluntary or uncertified patients are admitted.
Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise. The Committee will also consider applications for admission at lower rates, and in certain cases will be prepared to admit patients free of charge.
Every facility for specialized investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit. In this Unit is found *X*-Ray and Dental Departments and the Bio-Chemical, Pathological, and Psychological Laboratories.
Furthermore, provision is made for Electro-Therapy and Hydro-Therapy to be carried out in all their forms, and Occupational Therapy under competent instruction is encouraged.
In addition to the Resident Medical Staff, Consultants in special branches of medicine and surgery are available whenever required.
The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms.
For forms and further particulars apply to the Physician-Superintendent at the Hospital

RUTHIN CASTLE, NORTH WALES

The fees are from 15 guineas a week. They include medical attendance, all scientific investigations that may be needed, such as analyses, bacteriological cultures, the ordinary *x*-ray examinations, and electrocardiograph readings; all treatment that may be prescribed such as special diets, insulin, artificial sunlight, electrical treatment, baths, massage nursing; medicines or vaccines, board and lodging.

The only extra charge is that for a complete alimentary *x*-ray examination, or for *x*-ray therapy.

All the usual forms of treatment are given at Ruthin Castle. The climate is mild. The annual rainfall is 30.5 inches that is, less than the average for England. There is central heating throughout.

Address—THE SECRETARY, Ruthin Castle, North Wales. *Telegrams*—Castle, Ruthin. *Telephone*—Ruthin 66

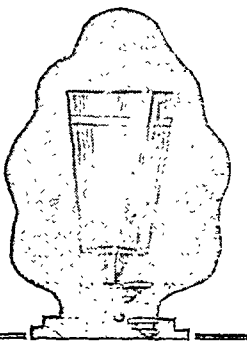
Choose a Spa in Czechoslovakia...

The Spas and Health Resorts of Czechoslovakia, with their centuries-old tradition of healing, reinforced by the experience and researches of local specialists, invite your serious consideration.



In addition to places of world-wide repute such as:

PISTANY (Piestany) **CARLSBAD** (Karlovy Vary) **MARIENBAD** (Mariánské Lázne) **FRANZENSBAD** (Františkovy Lázně)

ST. JOACHIMSTHAL (Jachymov) **TEPLICE-SANOV** (Teplitz-Schönau) **LUHAČOVICE** **SLIAČ** **TRENČIANSKE-TEPLICE**

with their medicinal springs and mud baths, there are numerous smaller spas and health resorts admirably equipped for the treatment of many diseases, including those in the following groups:

ANAEMIA AND CHLOROSIS.
BASEDOW'S DISEASE.
BRONCHIAL CATARRH.
CONSTITUTIONAL DISEASES. SCROFULA, RICKETS.
DIGESTIVE DISEASES.
DISEASES OF THE BLADDER AND URINARY ORGANS.
DISEASES OF THE KIDNEYS
DISEASES OF THE NOSE AND THROAT.
DISEASES OF WOMEN.
DISORDERS OF BONES, MUSCLES, AND JOINTS.
DISORDERS OF THE HEART
DISORDERS OF METABOLISM AND GOUT.
GALLSTONES.
LEUCAEMIA.
NERVOUS DISEASES AND POST HEMIPLEGIC CONDITIONS.
TUBERCULOSIS OF THE LUNGS

The arrangements in the bath establishments are up-to-date in every way, the cleanliness and neatness proverbial, the service attentive and courteous.

It is accepted that a spa cure to be fully beneficial should provide a complete change of surroundings, and a break with the patient's normal everyday life.

The Czechoslovak Spas fulfil this purpose admirably . . . comfortable hotels . . . first-class orchestras and dance bands . . . every facility for sport—tennis, golf, swimming, riding, fishing, etc.

There are also numerous fully up-to-date homes for convalescence and rest cures

For travel information, descriptive brochure, etc., apply to:

Tel.: Welbeck 8901

PROVIDES HIGHLY SUCCESSFUL ORAL AND POSTAL COACHING FOR ALL MEDICAL EXAMINATIONS

Special Preparations for all Surgical Qualifications.

F.R.C.S.ENGLAND. M.C.CANTAB.
(Primary & Final). M.S.LONDON.
F.R.C.S.EDINBURGH.

And all other Surgical Degrees and Diplomas.

¶ The remarkable success of Students of the Medical Correspondence College at the higher Surgical Examinations is specially noteworthy.

¶ Both at the Primary and Final F.R.C.S.England the majority of our Students are successful at the first attempt, and Candidates who have failed at these Examinations on several previous occasions get through without difficulty after going through our courses.

¶ The Surgical Tutors of the College all hold either the M.S.Lond. or F.R.C.S.England, or both, and are highly experienced teachers.

¶ The Postal Courses are thoroughly clear, concise, and *up to date*, and the test *questions* are carefully selected from those set at previous Examinations, so as to embrace all parts of the subject. By working systematically through the Course the Student is brought up to the examination standard in the minimum time, and much unnecessary reading is saved.

SURGEONS' HALL, EDINBURGH

ANATOMY

The VACATION CLASSES commence on AUGUST 3RD and terminate SEPTEMBER 29TH. Lectures and Demonstrations covering the entire subject, and including Embryology, are given thrice daily.

Names can be enrolled on early application to CHAS. R. WHITTAKER, F.R.C.S., F.R.S.E., Lecturer.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE, CARDIFF

The Council of the College invites applications for the appointment of an ASSISTANT LECTURER in the DEPARTMENT OF ANATOMY, at a salary of £500 per annum.

Further particulars may be obtained from the undersigned, by whom three copies of application (which need not be printed) must be received not later than July 7th, 1937.

LOUIS S. THOMAS,
University College, Cardiff. Registrar.
June 14th, 1937.

HIS MAJESTY'S COLONIAL SERVICE

COLONIAL MEDICAL SERVICE.

A vacancy exists in TRINIDAD for a MEDICAL OFFICER OF HEALTH (VENEREAL DISEASES SERVICE).

Qualifications.—Candidates must be British subjects and possess a medical qualification registrable in the United Kingdom. They must hold the Diploma of Public Health and have had special experience in the treatment and administration of venereal diseases.

Duties.—Attendance at Venereal Diseases Clinics and the treatment and administration of venereal disease; propaganda and educational work in districts when required, and such other public health duties as may be prescribed by the Director of Medical Services. The officer appointed may be required to serve in any district in the Colony.

Salary.—£600 a year, rising by £25 to £800.

Terms of Appointment.—The appointment is pensionable, but the officer will be on probation for two years. Private practice will not be allowed.

Quarters.—A housing allowance of £100 a year is payable.

Passages.—The selected candidate, who will be required to proceed to Trinidad as soon as possible, will be provided with free first-class ocean *passages for himself and his family, not exceeding* five persons in all, on first appointment. Leave passages are not provided. Further particulars and forms of application may be obtained from the DIRECTOR OF RECRUITMENT (Colonial Service), 2, Richmond Terrace, Whitehall, London, S.W.1.

CITY OF NOTTINGHAM

ASSISTANT SURGICAL OFFICER—City Hospital.

Applications are invited from duly qualified Medical Practitioners for the post of Assistant Surgical Officer at the City Hospital (981 beds).

Salary £250 per annum, with board-residence, laundry.

Appointment will be for six months, with a prospect of renewal for a further six months.

The duties will be chiefly surgical, under the direction of a staff of visiting-surgeons, and subject to the control of the Medical Superintendent. Applicants should have had previous Hospital experience.

The appointment will not be subject to the Corporation's Superannuation Scheme.

Application forms and further particulars may be obtained from the undersigned, to whom they should be returned forthwith.

The appointed officer to commence duties at earliest opportunity.

Canvassing, directly or indirectly, is forbidden.

J. E. RICHARDS,
The Guildhall, Nottingham. Town Clerk.
June 28th, 1937.

COUNTY BOROUGH OF PRESTON.

SHAROE GREEN HOSPITAL. (250 Beds.)

JUNIOR ASSISTANT RESIDENT MEDICAL OFFICER (female). Applications are invited from fully qualified and registered practitioners for the above appointment. Salary at the rate of £100 per annum, with full board and residence. The appointment will be for a period of six months, and at the end of this period the successful applicant may, subject to satisfactory service, be promoted to the post of Senior Assistant Resident Medical Officer for a further period of not more than six months.

Applications, stating age, qualifications and experience, together with copies of three recent testimonials, should reach the Medical Superintendent not later than first post on Saturday, July 24th, 1937.

THE KING EDWARD VII WELSH NATIONAL MEMORIAL ASSOCIATION.

ASSISTANT TUBERCULOSIS MEDICAL OFFICER (Resident)

Applications are invited from duly registered medical practitioners (male, single) for the post of Assistant Tuberculosis Medical Officer (Resident) at the Sully Hospital, Sully, Glam. (300 beds for the treatment of pulmonary tuberculosis), situate between Penarth and Barry.

Salary £500 per annum, rising by annual increments of £25 to £700 per annum, less the value of emoluments amounting to £100 per annum.

Preferably candidates should have had six months' resident experience in a special Institution (hospital or sanatorium) for the treatment of pulmonary and/or non-pulmonary tuberculosis, with eighteen months' experience in general clinical work, of which six months should have been spent in a hospital not confined to the treatment of tuberculosis. Experience in anæsthetics also desirable.

The person appointed to the above post will be required to pass a medical examination and to contribute 5 per cent. of his salary to the Superannuation Fund of the Association. Applicants not already in the service of the Association must be under 45 years of age.

Applications, stating age, qualifications, experience, etc., together with copies of three recent testimonials, should reach the undersigned not later than Thursday, July 15th, 1937.

Memorial Offices, D. A. POWELL,
Westgate Street, Principal Medical Officer.
Cardiff.

COUNTY BOROUGH OF CROYDON.

PUBLIC HEALTH DEPARTMENT.

APPOINTMENT OF ASSISTANT MEDICAL OFFICER FOR OBSTETRICS.

Applications are invited from qualified Medical Men or Women for the post of ASSISTANT MEDICAL OFFICER FOR OBSTETRICS. Candidates must have had practical hospital experience in Gynæcology and Obstetrics, and of ante-natal and post-natal clinics.

The appointment will be for twelve months, and the salary will be £300 per annum, with board, residence and laundry valued at £140. The successful candidate will have quarters at Mayday Hospital, Thornton Heath.

The Officer appointed will be on the staff of the Medical Officer of Health, and work under his administrative supervision.

Application forms may be obtained from the Medical Officer of Health, Town Hall, Croydon, on receipt of a stamped, addressed foolscap envelope, and should be returned to him not later than 11 a.m. on Monday, July 19th, 1937, together with copies of three testimonials of recent date. Canvassing in any form is prohibited.

Town Hall, JOHN M. NEWNHAM,
Croydon. Town Clerk.
June 23rd, 1937.

BRIDPORT AND LYME REGIS BOROUGHS, BRIDPORT AND BEAMINSTER RURAL DISTRICTS.

Applications are invited for the appointment of MEDICAL OFFICER OF HEALTH for the above united District, the approximate population of which is 23,409. The Officer appointed must hold the D.P.H. and will be required to reside in the District and devote his whole time to the work. He will also be required to provide duly qualified Locum Tenens while he is on holiday.

Salary £800 per annum; in addition an allowance of £50 per annum will be paid for travelling and subsistence expenses.

The appointment will be subject to the approval of the Ministry of Health and may be determined on either side at any time on three months' notice.

Applications, stating age, qualifications, and experience, together with copies of three recent testimonials, should be sent to the Town Clerk, Bridport, Dorset, to whom any enquiries relating to the appointment should be addressed. Last day for receipt of applications, July 5th.

Canvassing directly or indirectly, will disqualify.

G. EDGAR HOWARD,
Town Clerk, Bridport.
Town Clerk's Office, Bridport.
Dated June 23rd, 1937.

ROYAL AIR FORCE MEDICAL SERVICE

Applications are invited from medical men for appointment to commissions in the Medical Branch of the Royal Air Force for entry in September, 1937.

Candidates must be of pure European descent. They must be British Subjects, the sons of British Subjects and registered under the Medical Acts.

Candidates must be under *28 years of age* and will be selected after interview by a selection board without competitive examination.

Hospital appointments held since qualifying will, under certain conditions, qualify candidates for antedate of commission up to a maximum of one year; the age of entry may, if necessary, be increased by a period equal to the "antedate."

Selected candidates will be appointed to short service commissions (for 3 years extendible to 5 years) followed by 4 years' service in the Reserve, and will be eligible to be considered for Permanent Commissions during their second or third year of service. Officers not selected for permanent commissions receive gratuity as follows, on transferring to the Reserve:—

On completion of 3 years—£400.
On completion of 5 years—£1,000.

Copies of the regulations for entry and conditions of service, including rates of pay and allowances, also form of application, may be obtained on application from:—

The Secretary,
Air Ministry (D.M.S.),
Adastral House,
Kingsway, W.C.2.

Completed applications from intending candidates for the vacancies in September, 1937, must be received in the Air Ministry not later than the 15th of July, 1937.

ROYAL NAVAL MEDICAL SERVICE.

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in October, 1937.

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years in the first instance, which may be extended to five years at the discretion of the Admiralty.

At the end of three years' service officers may retire with a gratuity of £400, but those who serve for five years will receive £1,000.

At the end of five years' Short Service permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Opportunities are available for officers on the permanent list to specialise, and ample provision is made for Post-Graduate study.

Copies of the regulations for entry and conditions of service, including rates of pay and allowances, may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than August 31st, 1937.

COUNTY COUNCIL OF MIDDLESEX.

SURGEON—GRADE I., WEST MIDDLESEX COUNTY HOSPITAL, ISLEWORTH.

Applications are invited from registered Medical Practitioners for the above appointment on the pensionable staff. The appointment is a senior one in the Council's general hospital service and applicants are expected to be medical men or women of high qualification and professional attainments, who are devoting their time wholly or chiefly to the practice of general surgery. The officer appointed will work under the direction of the Medical Superintendent of the Hospital and will give his whole time to the duties of the post. He must be prepared to undertake the teaching of students if required, and to carry out such other duties as the County Council may from time to time direct.

The Hospital has some 1,350 beds, about 600 of which are devoted to the treatment of acute conditions. There is a separate maternity wing, a pathological laboratory and animal house, and departments of orthopaedics, radiology, electrotherapy and ophthalmology.

Salary £1,000 per annum, rising by annual increments of £50 to £1,500 per annum. The salary is inclusive and any fees received by the officer appointed must be paid over to the County Council.

The appointment is non-resident, but the successful candidate will be required to reside within a short distance of the Hospital. The appointment, which will be subject to medical examination, will be held during the pleasure of the Council, and is terminable by three months' notice on either side.

Applications, stating age, qualifications and experience, together with copies of not more than three recent testimonials, must be received by the undersigned not later than July 10th. Relationship to any member or officer of the Council must be disclosed in the application. Application forms are not provided. Envelopes must be endorsed "Surgeon, West Middlesex County Hospital."

Canvassing, directly or indirectly, will be a disqualification.

C. W. RADCLIFFE, "Z."
Clerk of the County Council.

Middlesex Guildhall, Westminster, S.W.1.
June 14th, 1937.

CITY OF PORT-OF-SPAIN.

APPOINTMENT OF A MEDICAL OFFICER OF HEALTH.

The Port-of-Spain City Council invite applications for the post of Medical Officer of Health for the City of Port-of-Spain.

The duties of the office are as set forth in the bye-laws made by the Central Board of Health and published in the Trinidad Royal Gazette of October 25th, 1917, page 1975-77.

Every applicant must be, or entitled to be, a member of the Medical Board of Trinidad and shall be the possessor of a Diploma of Public Health, Sanitary Science or State Medicine, registered or entitled to be registered in Great Britain and Ireland.

The office is a whole time one and pensionable under the provisions of the Municipal Corporations (Pensions) Ordinance, No. 29 of 1936. The salary attached to the post is £800 per annum, rising by equal annual increments of £25 to £1,000, with a travelling allowance of £75 a year.

The person appointed will be required to furnish a bond in the sum of £100 for the due performance of his duties.

Applications, stating age, qualifications and experience, should reach the undersigned at the Town Hall, Port-of-Spain, Trinidad, B.W.I., not later than July 31st, 1937.

The Town Hall, Port-of-Spain, Trinidad, B.W.I.
April 29th, 1937.

E. PRADA,
Town Clerk.

SUNDERLAND EDUCATION COMMITTEE.

APPOINTMENT OF ASSISTANT SCHOOL DENTIST (MAN).

The Committee invites applications from duly qualified Dental Surgeons, not more than 35 years of age, for the post of Assistant School Dentist

The person appointed will be responsible, under the Chief School Medical Officer, for the Dental Inspection and Treatment of school children and will be required to devote his whole time to the duties of the office.

Salary £450 per annum.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the selected candidate will be required to pass a medical examination.

Applications, to be made on forms which may be obtained from the undersigned, must be returned on or before Wednesday, July 14th, 1937, accompanied by copies of not more than three recent testimonials.

Canvassing will be a disqualification.

W. THOMPSON,
Director of Education.

Education Offices, 15, John Street, Sunderland.
June, 1937.

COUNTY COUNCIL OF MIDDLESEX.

SENIOR DENTAL OFFICER.

Applications are invited for the above appointment on the pensionable staff. Applicants must be fully qualified and registered dental surgeons of wide experience.

The duties of the post include the dental inspection and treatment of school children, and of women and young children under the Council's maternity and child welfare scheme, the supervision of the work of the Council's staff of assistant dental officers, and such other clinical or administrative duties as the County Council may from time to time direct.

The officer appointed will be required to commence duty on October 11th, 1937, to devote his whole time to the duties of the post, will not be allowed to engage in private practice, and will work under the supervision of the County Medical Officer.

Salary £700 per annum, rising by annual increments of £25 to £900, together with out-of-pocket travelling expenses while on duty.

The appointment, which will be subject to medical examination, will be held during the pleasure of the Council, and is terminable by three months' notice on either side.

Applications, stating age, qualifications and experience, together with copies of not more than three recent testimonials, must be received by the undersigned not later than July 10th. Relationship to any member or officer of the Council must be disclosed in the application. Application forms are not provided. Envelopes must be endorsed "Senior Dental Officer."

Canvassing, directly or indirectly, will be a disqualification.

C. W. RADCLIFFE, "Z."
Clerk to the County Council.

Middlesex Guildhall, Westminster, S.W.1.
June 17th, 1937.

BOROUGH OF ILFORD.

APPOINTMENT OF
(a) ASSISTANT MEDICAL OFFICER OF HEALTH (male);
(b) ASSISTANT MEDICAL OFFICER OF HEALTH (female).

Applications are invited from legally qualified medical practitioners for the undermentioned whole-time appointments:

(a) ASSISTANT MEDICAL OFFICER OF HEALTH (male), at a commencing salary of £500 per annum, rising by annual increments of £25 to a maximum of £700 per annum for duties in connection with the Maternity, Child Welfare and School Medical Services, and other Public Health work. Candidates must possess the Diploma of Public Health or similar qualification.

(b) ASSISTANT MEDICAL OFFICER OF HEALTH (female), at a commencing salary of £400 per annum, rising by annual increments of £25 to a maximum of £550 per annum, with free board and residence at the Corporation's Isolation Hospital, for duties in connection with Maternity and Child Welfare work, School Medical Inspection, and general Public Health work. Candidates must possess the Diploma of Public Health or similar qualification.

Both the above appointments will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and to formal agreement, and the selected applicant will be required to pass a medical examination by and to the satisfaction of the Medical Officer of Health. The appointment will also be subject to three months' notice on either side.

Applications on the prescribed form, obtainable from my office, must be received by me at the Town Hall, Ilford, not later than Tuesday, July 6th, 1937.

Canvassing, directly or indirectly, will be a disqualification.

Town Hall, Ilford.
June 22nd, 1937.

CHARLES N. ROBERTS,
Town Clerk.

COUNTY BOROUGH OF OLDHAM.
Municipal Hospital.

RESIDENT ASSISTANT MEDICAL OFFICER.

Applications are invited from registered Medical Practitioners for the post of Resident Assistant Medical Officer.

Salary £200 per annum, with board, residence and laundry.

Candidates should be unmarried.

The appointment will, in the first instance, be for a period of six months. The successful applicant, however, will be eligible for reappointment for a further period of six months.

The Hospital comprises 375 beds, with facilities for gaining experience in medicine, surgery, midwifery, and diseases of children.

Application forms may be obtained from the Medical Officer of Health, Town Hall, Oldham, and should be returned, endorsed "Resident Assistant Medical Officer," as soon as possible, but not later than Monday, July 12th, 1937.

JOSEPH J. WILLIAMS, LL.D.,
Town Clerk.

Town Hall, Oldham.
June 21st, 1937.

COUNTY COUNCIL OF MIDDLESEX.

ASSISTANT PATHOLOGIST.

Applications are invited for the pensionable appointment of ASSISTANT PATHOLOGIST to WEST MIDDLESEX COUNTY HOSPITAL, ISLEWORTH. Candidates must be registered Medical Practitioners, with special knowledge and experience in pathology, who are engaged wholly or chiefly in the practice of this branch of medicine.

The officer appointed must devote his whole time to the duties of his office. He will not be allowed to engage in private practice, and any fees received by him must be paid over to the Council. The appointment, which will be subject to medical examination, will be held during the pleasure of the Council, and is terminable by three months' notice on either side.

Salary £650 per annum, rising by annual increments of £25 to £800 per annum.

Applications, stating age, qualifications, and experience, together with copies of not more than three recent testimonials, must be received by the undersigned not later than July 10th. Application forms are not provided. Envelopes must be endorsed "Assistant Pathologist, West Middlesex County Hospital."

Canvassing, directly or indirectly, will be a disqualification.

C. W. RADCLIFFE "Z."
Clerk of the County Council.

Middlesex Guildhall, Westminster, S.W.1.
June 17th, 1937.

COUNTY BOROUGH OF CROYDON.

PUBLIC HEALTH DEPARTMENT.

APPOINTMENT OF ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER

Applications from qualified Medical Practitioners are invited for the appointment of an Assistant Medical Officer of Health and Assistant School Medical Officer.

Applicants must be Medical Men holding a special qualification in State Medicine, or a Diploma in Public Health, and must have had three years' experience of the practice of medicine since obtaining their medical qualifications.

Preference will be given to applicants who:
(a) Have had some definite experience of School Medical work;
(b) Have enjoyed special opportunities for the study of the Diseases in Children;
(c) Have had experience in Infectious Diseases; and
(d) Have held one or more Resident Hospital appointments.

The candidate appointed will be required to produce a recent satisfactory medical certificate of health, and to devote the whole of his time to the duties of the office.

The salary will be £500 per annum, rising by annual increments of £25 to a maximum of £700 per annum.

The post is designated under the Local Government and Other Officers' Superannuation Act, 1922, and deductions will, therefore, be made for superannuation purposes.

Application forms may be obtained by sending a stamped addressed foolscap envelope to the Medical Officer of Health, Town Hall, Croydon, to whom they should be returned, together with copies of three testimonials of recent date, not later than 11 a.m. on Monday, July 12th, 1937.

Canvassing in any form will be a disqualification.

Town Hall, Croydon.
June 16th, 1937.

JOHN M. NEWNHAM,
Town Clerk.

BURY INFIRMARY (LANCS)
(143 Beds.)

RESIDENT SURGICAL OFFICER (MALE).

Applications are invited for the above post from those holding the Fellowship of one of the Royal Colleges of Surgeons.

The appointment is for a term of one year, with provision for an extension of a further twelve months, and the successful candidate will be expected to commence duties at the beginning of July.

Salary will be paid during the first twelve months at the rate of £300 per annum, and will be increased to £350 per annum during the second twelve months in the event of an extension of the appointment being agreed upon. In addition to this salary the post includes the provision of board-residence and laundry.

Applications, stating age, qualifications and nationality, together with copies of three recent testimonials, are to be addressed to the undersigned, and should be forwarded as soon as possible, endorsed "R.S.O."

H. WILKINSON,
Superintendent.

KNOWLE MENTAL HOSPITAL, FAREHAM, HANTS.

Applications are invited for the post of JUNIOR ASSISTANT MEDICAL OFFICER.

Applicants should be Male and single, and under 35.

The salary is £350, rising by yearly increments of £25 to £450, with board, lodging, washing and attendance, valued at £150.

The possession of a Diploma in Psychological Medicine entitles the holder to an extra £50 per annum.

The salary is subject to deduction under the Asylums Officers' Superannuation Act, 1909.

Applications, stating age, and all particulars, accompanied by copies of three recent testimonials, should be sent to the Medical Superintendent not later than July 17th.

BURY INFIRMARY (LANCS.)
(127 Beds.)

APPOINTMENT OF CASUALTY OFFICER (MALE).

A vacancy as above arises on the Resident Medical Staff, and applications are invited for the post.

The Resident Staff consists of an R.S.O., a House Surgeon, and House Physician, and a Casualty Officer.

In addition to his duties in the Casualty Department the Casualty Officer is also responsible for the In-patient and Out-patient work in connection with the Eye, and Ear, Nose and Throat Department.

The appointment is for six months at a salary at the rate of £150 per annum, with board, residence and laundry, and the successful candidate will be expected to commence duties immediately.

Applications, stating age, qualifications, and nationality, together with copies of three recent testimonials, are to be forwarded to the undersigned as soon as possible, endorsed "Casualty Officer."

Further particulars may be had on application

H. WILKINSON,
Superintendent.

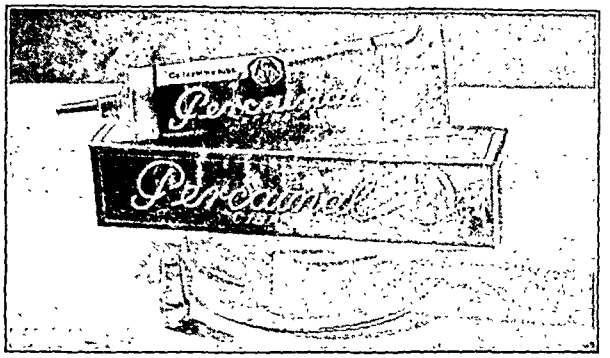
Samples and Literature



In many of the advertisements appearing in these pages an offer is made to send samples and descriptive literature to interested readers. The cost of this to the advertiser may amount to 6s. 0d. or even more for replying to a single inquiry.

At the same time, firms with confidence in the value of their products are happy to provide, in this way, an opportunity for practical tests without cost to the doctor. Such firms are always keen to hear of actual results and to receive any suggestions for improvement in the products themselves or the method of their use.

By co-operating with these undertakings you directly encourage the ethical firms whose advertisements alone are accepted for the *British Medical Journal.*

Issued by the British Medical Journal in the joint interests of readers and advertisers.

CAUTION

To attract the attention of sufferers from rupture, there appear from time to time in the press specious advertisements of some "wonderful new appliance" or pretended new mode of treatment.

SALMON ODY Ltd., whose house has devoted itself for over 100 years to the manufacture of Trusses, find it necessary in the interests of the community—

TO WARN THE PUBLIC against these **Quack Advertisements** and to urge the advisability of an examination by a qualified medical man when the trouble appears, and, in the selection of a Truss, the necessity of having recourse to none but **Trussmakers of Established Reputation.**

Most of our clients are sent to us by their Medical advisers.

Salmon Ody Trusses can only be obtained from the Originators, Patentees, Sole Makers, AND NOWHERE ELSE

Telephone: Holborn 3805.

'Elastoplast' in the treatment of Fractured Ribs

Bandaging with 'Elastoplast' provides ideal support for fractured ribs. An 'Elastoplast' bandage, 3 inches wide, 5/6 yards long is used, and applied cummerbund fashion if possible, using a moderate degree of tension. If it is for any reason impossible to encircle the body completely, strips of the bandage, which should be as long as possible, are applied, well over and beyond the site of the fracture. Each layer or turn of 'Elastoplast' is applied at the moment when the patient has expired fully.

Particulars of this and many other uses of 'Elastoplast' are given in "Elastoplast Technique," a copy of which will be sent on request.

THE PRACTITIONER

EDITED BY

Sir Humphry Rolleston, Bt., G.C.V.O., K.C.B., M.D., F.R.C.P., and Alan Moncrieff, M.D., F.R.C.P.

Founded in the  *Year 1868*

A programme of great interest and service to the general practitioner is offered every month by *The Practitioner*. Each issue is planned to assist in the day-to-day problems that confront every doctor, and the exhaustive character and high quality of the articles, written by eminent physicians and surgeons, are such as to provide the most reliable guidance in diagnosis and treatment.

Recent issues and forthcoming numbers cover a wide field of medical practice and embrace articles on the following subjects:

GYNÆCOLOGY (January, 1937)
GASTRO-INTESTINAL DISORDERS (February)
POST-OPERATIVE CARE AND CONVALESCENCE (March)
USE AND ABUSE OF DRUGS. *Special Number* (April)
DISEASES OF THE HEART (May)
CARE OF THE PRE-SCHOOL CHILD (June)
CARE OF THE AGED (July)
TROPICAL DISEASES, AIR RAID PRECAUTIONS, POISONING (August)
MEDICAL ASPECTS OF MOTORING (Accidents, etc.) (September)
ADVANCES IN DIAGNOSIS AND TREATMENT 1936-37. *Special Number* (October)

DIET IN HEALTH AND DISEASE.

The July number contains the first article in a series on diet which will continue, one in each number, for eighteen months. Each article will contain as far as possible specimen menus in a form suitable for practitioners to copy out for their patients. Professor V. H. Mottram contributes the opening article which is entitled "Practical Dietetics."

Special numbers 7s. 6d. .. .. Ordinary numbers 4s.
Annual subscription £2 2s. post free to any part of the world.

SAUNDERS' BOOKS

ALL of REAL HELP in PRACTICE

BERENS' EYE DISEASES

By 82 of the WORLD'S LEADING AUTHORITIES. Octavo of 1254 pages, with 436 illustrations, some in colours. Edited by CONRAD BERENS, M.D., Ophthalmic Surgeon, Pathologist, and Director of Research, New York Eye and Ear Infirmary. Cloth, 50s. net.

". . . the book is certainly all that is claimed for it. It presents the essentials of ophthalmology to physicians, surgeons, medical students and those entering upon the practice of ophthalmology. The subject-matter is presented in a style that makes it eminently readable, and so well are the different sections arranged that one easily forgets that it is the work of eighty-two different contributors." —Irish Journal of Medical Science.

PHYSICAL DIAGNOSIS

By RALPH H. MAJOR, M.D., Professor of Medicine in the University of Kansas. Octavo of 475 pages, 427 illustrations. Cloth, 21s. net.

"Professor Major has produced a book which is both readable and serviceable, and which, while paying tribute to the ancient learning, does not fail to give a place to modern values." —British Medical Journal.

CLINICAL HEART DISEASE

By SAMUEL A. LEVINE, M.D., F.A.C.P., Assistant Professor of Medicine, Harvard Medical School. Octavo of 450 pages. Cloth, 24s. net.

". . . is an interesting book. The matter is largely drawn from the author's experience, and he freely states his own point of view and ideas. The book does not follow any special plan. The subjects are chosen and dealt with independently, in view of their practical importance. In fact, practical considerations have first place all through this work. . . . The book may be read with profit." —British Medical Journal.

DISEASES OF INFANTS AND CHILDREN

By J. P. CROZER GRIFFITH, M.D., Ph.D., Emeritus Professor of Pediatrics, University of Pennsylvania; and A. GRAEME MITCHELL, M.D., B.K.Rachford, Professor of Pediatrics, College of Medicine, University of Cincinnati. One octavo of 1154 pages, with 293 illustrations, including 18 plates in colours. *Cloth, 42s. net*

"There are few points indeed on which a reviewer can join issue with the writers; every school of opinion is fairly represented and fairly adjudged. . . . There are wonderful coloured illustrations of such important things as vaccination, tuberculin and Schick tests; stools in various conditions, etc. . . . The subject could not have found better exponents." —Irish Journal of Medical Science.

ENDOCRINOLOGY IN MODERN PRACTICE

By WILLIAM WOLF, M.D., M.S., Ph.D. Octavo of 1018 pages, with 253 illustrations. Cloth, 42s. net.

"The section on diagnosis is constructed on a practical plan, with a suggested order of examination and an interpretation of the value of laboratory findings. We would specially call attention to the chapter on bone development. Not many of us can carry in our memories the dates of the appearance of centres of ossification or of epiphyseal junctions. The series of skiagrams illustrating such facts form a valuable picture gallery for ready reference." —British Medical Journal.

MEDICAL TREATMENT OF GALL-BLADDER DISEASE

By MARTIN E. REHFUSS, Professor of Clinical Medicine at Jefferson Medical College; and GUY M. NELSON, M.D., Instructor of Medicine at Jefferson Medical College. Octavo of 465 pages, illustrated. Cloth, 24s. net.

"Treatment . . . includes a general medical régime, the use of special diets, attention to focal sepsis, internal biliary drainage, and the administration of specific cholagogues and choloretics. The indications for these various forms of therapy, and the details to be observed in carrying them out, are described with a wealth of detail. The book is attractively produced, well illustrated, and can be recommended." —Edinburgh Medical Journal.

Crn. Quarto. 312 pages with 172 Illustrations. Price 21s. net. Postage 7d.

This volume, dealing with the medico-legal and other scientific aspects of ... sponse to numerous requests from members of the medical and legal professions ... tended for those professionally interested in methods employed in the preparatio ...

LATEST NEW BOOKS AND NEW EDITIONS

MUIR'S "BACTERIOLOGICAL ATLAS." Revised by C. E. van ROOYEN, M.D, Halley Stewart Research Fellow and Lecturer in Bacteriology in the University of Edinburgh. **Second Edition,** containing 83 Coloured Plates faced by descriptive text. Price 15s. net. Postage 6d. (Pub. June, 1937)

The 83 Coloured Plates in the new edition of this Atlas illustrate 91 organisms. Twenty-six of the Plates are entirely new and all are fully described in the Text.—*Publishers Note.*

"DISEASES OF THE NOSE, THROAT AND EAR." By I. SIMSON HALL, M.B., F.R.C.P., F.R.C.S., Surgeon, Ear, Nose and Throat Department, Royal Infirmary, Edinburgh. 420 pages, 55 Illustrations and Coloured Frontispiece. Price 15s. net. Postage 6d. (Pub. March, 1937)

One of the commendable features of the book is the anatomic ... various sections, and these are illustrated by some useful diagrams; an outstanding feature of the book is the series ... l excellent. In conclusion, it can be said that it is a most excellent book, ... will probably regard it as the most suitable book on this subject for the M.B., Ch.B. examination.—*The Student.*

LEES' PRACTICAL METHODS IN THE DIAGNOSIS AND TREATMENT OF VENEREAL DISEASES. Revised by ROBERT LEES, M.B., F.R.C.P., and other Contributors. **Third Edition.** 624 pp., 85 Illustrations, with 8 pp. of Coloured Plates. Price 15s. net. Postage 6d. (*Pub. January,* 1937)

"Students and general practitioners will find all that they need in this admirable book, which contains a wealth of information in a comparatively small compass. The names of the authors and their wide experience of the subjects with which they deal are sufficient guarantee of the accuracy of the contents of a book which has been brought up to date. Methods of treatment and diagnosis are constantly changing so that a new edition is to be welcomed, and this one is a marked improvement on its two predecessors."—*The British Medical Journal.*

A HANDBOOK OF DISEASES OF CHILDREN. Including Dietetics and Common Fevers. By BRUCE WILLIAMSON, M.D.(Ed.), M.R.C.P.(Lond.). **Second Edition.** 340 pp., 61 Illustrations and Frontispiece. Price 10s. 6d. net. Postage 6d. (*Pub. Nov.* 1936)

"Dr. Williamson has accomplished his task of making a short but complete account of the diseases and disorders of infancy and childhood in a thoroughly satisfactory manner, and has provided a book the features of which are both attractive and distinctive; this book will undoubtedly become well known."—*Edinburgh Medical Journal.*

TEXTBOOK OF MEDICINE. Edited by J. J. CONYBEARE, M.D.(Oxon.), F.R.C.P. Compiled by Fifteen Contributors. **Third Edition.** 1050 pp. Illustrated with Diagrams and X-ray Plates. Price 21s. net. Postage 7d. (*Pub. October,* 1936)

"As medicine is making such rapid progress in many departments, it is essential that textbooks for ... should be frequently revised and ... encourage their use. These latte... Medicine. This volume gives a concise, accurate, and most readable account of the various diseases, their pathogenesis and treatment, and we are convinced that it will continue to occupy a foremost place among the textbooks on medicine of to-day."—*Post Graduate Medical Journal.*

"THE CATECHISM SERIES." 65 Parts at 1s. 6d. per part: *List on application.*

"There are fully 20,000 questions asked and answered in this series and the Parts are being continually revised and brought up to date."—*Publishers Note.*

MANUAL OF PUBLIC HEALTH — "Laboratory Practice." By J. R. CURRIE, M.A.(Oxon.), M.D. (Glas.), M.A., M.R.C.P.(Edin.), D.P.H.(Birm.), Professor of Public Health, University of Glasgow, etc. Assisted by several Contributors. 400 pp., 169 Illustrations. Price 21s. net. Postage 7d. (1936)

"Not only is the volume suitable for those studying for examinations, it is also an excellent book for reference to be used on the laboratory bench. The tests are clearly described and the different steps easy to follow."—*The Journal of Tropical Medicine and Hygiene.*

PATHOLOGY OF THE NERVOUS SYSTEM. By J. HENRY BIGGART, M.D., Pathologist to the Scottish Asylums Board; Neuropathologist to the Royal Infirmary, Edinburgh. 350 pp., 204 Illustrations. Price 15s. net. Postage 6d. (1936)

"It is excellently illustrated and is written in an easy and facile style, the author making his facts stand out most vividly in the mind of the reader. We have no hesitation whatsoever in thoroughly recommending this book to the profession."—*Medical Press and Circular.*

HANDBOOK OF SURGERY. By ERIC C. MEKIE, M.B., Ch.B., F.R.C.S.(Ed.), formerly University Tutor, Royal Infirmary, Edinburgh; Assistant, Department of Clinical Surgery, University of Edinburgh. With a Foreword by Professor JOHN FRASER, M.D., Ch.M., F.R.C.S.E. 712 pp. Illustrated with diagrams. Price 12s. 6d. net. Postage 6d. (1936)

"We have nothing but the highest praise for this work. It may be said to represent an excellent summary of the current teaching of the Scottish school of surgery, and its appeal should be world-wide. The handbook comes from the house of Living-stone, whose reputation for the production of such works is already very high."—*British Medical Journal.*

COMBINED TEXTBOOK OF OBSTETRICS AND GYNAECOLOGY. By Professor MUNRO KERR, Dr. HAIG FERGUSON, Professor JAMES YOUNG, and Professor JAMES HENDRY, with other Contributors. **Second Edition.** 1120 pp., with over 500 Illustrations. Price 35s. net. Postage 9d. (Reprint 1936)

"All the teaching is on the soundest lines, as is only to be expected from the experience of its eminent authors. The illustrations are good, and our general impression of the book is that the present revision has very distinctly improved it."—*British Medical Journal.*

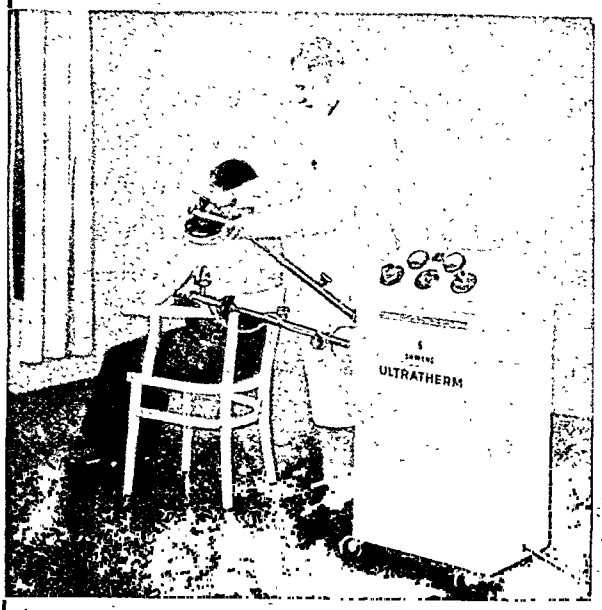
Wigmore Street, London, W.1.
DAY AND NIGHT SERVICE.
Telegrams and Telephone : Welbeck 5555.



European Agents for Baxter Laboratories Inc.:
GUY MAXWELL LIMITED,
Manfield House, Strand, London, W.C. 2.

TESTED:
Solutions in Vacoliter dispensers are prepared from a fractionated protein-free water. Their *p*H value is always consistent with their concentration. Baxter solutions are stable and sealed in vacuum and sterilized under recorded control. Each time a new solution is made up it is biologically tested. We ask you to give them a thorough clinical test. What you find out for yourself will be more eloquent than any claims we could possibly make.

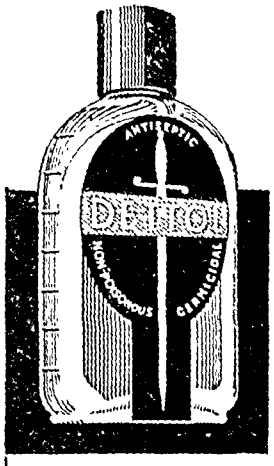
PETO-SCOTT
MAXADE
NEW MIDGET VALVE HEARING AID



The great service to the deafened of compensated valve amplification (*vide* Dr. A. W. G. Ewing, Mrs. J. R. Ewing and Dr. T. S. Littler, Privy Council Report, Series 219) is now available in Maxade Hearing Aids, with the additional advantages of variable compensation over the full range of speech frequencies, in an instrument as small and compact as scientific requirements and mechanical ingenuity will permit.

A variable "pitch" control permits the patient at all times to self-adjust the instrument to the individual degree of deafness—high, middle, or low. Interchangeable for either Air or Bone Conduction earpieces.

MAXADE ELECTRICAL Hearing Aids will gladly be sent for free clinical test to any member of the medical profession.

Instruments for clinical test and full information: please write to W. Scott-Worthington, Managing Director.
THE PETO-SCOTT COMPANY LTD. (Est. 1919), 77 City Road, London, E.C. 1. *Clissold 9575-6-7*

Proved efficiency with *pleasantness*

In spite of its high germicidal efficiency (Rideal-Walker 3.0) 'Dettol' can be used at strengths impracticable with carbolic and cresylic antiseptics. It is non-poisonous, non-staining, pleasant smelling. It has been shown that when 30% 'Dettol' is rubbed into the hands and allowed to dry the skin remains insusceptible to infection by haemolytic streptococci for at least two hours unless grossly contaminated. 'Dettol' is also stable in the presence of blood, pus, faeces and other organic matter.

Obtainable from chemists in 1/- and 3/- bottles; and in larger sizes for medical and hospital use.
(These prices do not apply in the Irish Free State and Overseas.) *Samples and full information on request.*

'DETTOL' TRADE MARK **THE MODERN ANTISEPTIC**

'DETTOL' will be exhibited at the B.M.A. Annual Exhibition, Stand No. 20, Ulster Hall, Belfast, July 19th—23rd.

Cap/105

Well-tried and successful dried milk foods, graded to suit bottle-feeding requirements from birth to weaning

OSTERMILK

NUMBER 1 & NUMBER 2

The formula of Ostermilk No. 1 approximates to that of human breast milk. Both the fat and protein content are diminished to suit the digestive capacity of the infant during the first months of life. It is suitable also for premature and weakly babies.

Ostermilk No. 2 is a full-cream, full protein dried milk, introduced usually at the third or fourth month (when the infant digestion is more strongly established) and is used thereafter for the remaining months of bottle-feeding.

The declared content of vitamin D in Ostermilk is a warrant that proper regard is paid to the importance of calcium metabolism. The incorporation of both vitamin D and iron in measured amounts provides factors which build not only for the present but for the future.

Constancy of composition and the greatest possible bacterial purity are accepted features of Ostermilk. Also, it is sold in sealed tins, a further protection against contamination.

Ostermilk is not a new product. It has been used for nine years in infant feeding, as a successful food, composed according to tried and proven formulæ, and manufactured by a firm with special experience in the production of infant foods. It maintains the high standard of all G.L. products at a price which makes it available through chemists, to every class of patient.

GONAN

It is stated frequently that the gonadotropic substances isolated from the urine of pregnancy consist almost entirely of prolan B, the luteinising factor.

Gonan is such a gonadotropic substance, but, in addition to its luteinising properties, it has pronounced follicle-stimulating properties. This fact is clearly demonstrated in the course of routine biological tests of Gonan in which marked growth of uteri and development of the ovarian follicles in the test animals is regularly observed.

Gonan is standardised in terms of its proliferational activity, which property, like its luteinising effect, is due to its content of prolan B.

Gonan is indicated, therefore, in the treatment of all forms of ovarian deficiency, whether follicles or corpora lutea are hyposecretory.

The importance of The Qualitative Adequacy of the Diet

". . . if the diet is unsuitable, the body cannot be properly constructed, neither can it function effectively."

(*Ministry of Health. First Report of Advisory Committee on Nutrition*, 1937, p. 6.)

The report quoted above stresses the need for ensuring that the whole community is provided with food which is qualitatively adequate. And it is acknowledged that foodstuffs containing vitamins play an important role in the economy of the body. Marmite is a yeast extract that is exceptionally rich in vitamin B_1 and the B_2 complex; it is prescribed extensively for its positive health-promoting properties. Marmite has many uses in preventive and curative medicine, and there is ample evidence of the benefit accruing from its regular inclusion in the diet.

"HIGHLY EFFICIENT . . . . COMPLETE ABSENCE OF SEPSIS"

Clinical reports on VERPINE show that it is an efficient, safe and pleasant germicide for general surgical purposes. The following is typical of the reports received:—

Dear Sirs,

Some time ago I received a sample of Verpine Antiseptic. I wish to inform you that I found it highly efficient. It was used for bathing and cleansing all kinds of injuries, many dirty, with complete absence of sepsis. *M.B., Ch.B.*

VERPINE has a Rideal-Walker co-efficient of 3, mixes readily with hot or cold water in any proportion, and has a pleasant, fresh odour. Its properties make it especially suitable for use in Gynaecology and Obstetrics.

VERPINE Regd. ANTISEPTIC AND GERMICIDE NON-POISONOUS

ALOCOL

Colloidal Hydroxide of Aluminium

Improved Antacid Therapy

SODIUM BICARBONATE, bismuth salts and other time-honoured antacids having each proved to possess individual disadvantages, an agent such as "Alocol" which combines the best therapeutic features of these with intrinsic merits of its own, must be of interest to the physician.

"Alocol" is a powerful antacid agent which forms with the stomach contents a colloidal jelly with the power of adsorbing free hydrochloric acid, thus fixing it and eliminating it from the system. It has a remarkably soothing effect on the inflamed or irritated gastric mucosa and is, therefore, rapidly effective in relieving pain. Being non-absorbable "Alocol" is free from any risk of "alkalosis."

"Alocol" can be prescribed with confidence in all cases where alkaline therapy is indicated. Issued in tablet and powder form.

Complete chemical history of "Alocol," with convincing clinical reports and supply for trial, sent free to physicians on request.

A. WANDER, Ltd., Manufacturing Chemists,
184, Queen's Gate, London, S.W.7.

Works: KING'S LANGLEY, HERTFORDSHIRE. M257

ALASIL

Safe Salicylate Therapy

THE popularity of acetyl-salicylic acid is undoubtedly due to the fact that it is one of the safest and most effective non-narcotic analgesics available. Too often, however, its use has been discarded by the physician on account of its tendency to irritate the stomach and because entirely pure preparations are not always available.

"Alasil" provides the beneficial therapeutic effects of pure acetyl-salicylic acid in such a form that it is acceptable even by disordered digestions. This tolerability is due to the fact that it combines calcium acetyl-salicylate—the least irritating salicylate compound—with "Alocol," a potent gastric sedative and antacid.

Since "Alasil" is better tolerated than acetyl-salicylic acid its use can be pushed or prolonged to a much greater extent than the latter. "Alasil" is, therefore, an analgesic, antipyretic, and antirheumatic which can be employed with complete confidence in all the many conditions in which such an agent is indicated.

A supply for clinical trial, with full descriptive literature, sent free on request.

A. WANDER, Ltd., Manufacturing Chemists,

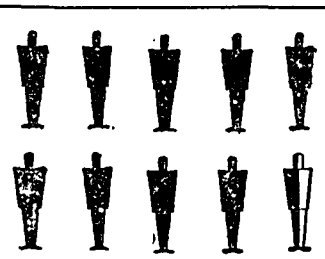
BRAN

effectively relieves

CONSTIPATION by STIMULATING

not forcing



NATURAL ACTION

7½D Per Packet

Medical men the world over are turning to Kellogg's ALL-BRAN as an effective and completely harmless constipation remedy. ALL-BRAN is easily digested and retains the valuable properties of the raw bran... assimilable iron and Vitamin B. ALL-BRAN cleanses like a *water-softened sponge*. Within the body the soft "bulk" of ALL-BRAN gently exercises intestinal muscles, and *sponges out* the system of waste matter.

Kellogg's ALL-BRAN is effective in all ordinary cases of constipation except those with hyper-sensitive alimentary tracts. It needs no cooking. Serve like any other cereal food or make into biscuits, cakes, omelettes, etc. Full-sized sample packet free on request.

98% cases of
CONSTIPATION
yield to the BRAN remedy

In laboratory tests, Bran has proved a definite remedy in 98 cases out of 100. The failures were all due to the patients' inability to accommodate bulk in fruit, vegetables or Bran.

ZANT

Before any Anæsthesia safeguard with Bisodol

For all types of anæsthesia, the pre-operative administration of alkalies is an effective preventative against post-operative acidosis and nausea.

•

Acidosis is one of the most common pathological conditions—indeed more common than fever.

•

BiSoDoL is a palatable preparation of balanced alkalies and digestive enzymes available either in powder or tablet form.

•

Write for samples and literature.

Instal a CASTLE STERILISER and be safe

The danger of using insufficiently sterilised instruments and appliances is too great to risk haphazard methods of sterilisation.

There are no risks when you use a Castle Full-Automatic Steriliser.

The basic equipment which forms part of every Castle sterilising outfit is the

MODEL C410

This model is obtainable as separate equipment in four sizes and possesses many valuable advantages :—

- ¶ It is "Full-Automatic"—runs itself.
- ¶ It saves time. Steriliser does not have to be watched.
- ¶ It uses only as much electricity as is actually needed.
- ¶ It has a cast bronze interior which assures a lifetime of unfailing service.

Cystopurin

The ideal biliary antiseptic

1 Produces no irritation or toxic effects.

2 Is readily absorbed.

3 Is active in either an acid or alkaline medium.

4 Renders the bile bactericidal and sterilises infected bile and the biliary passage.

5 Acts on causative organisms which may reach the biliary system through the systemic circulation and the alimentary tract.

6 Acts as a prophylactic.

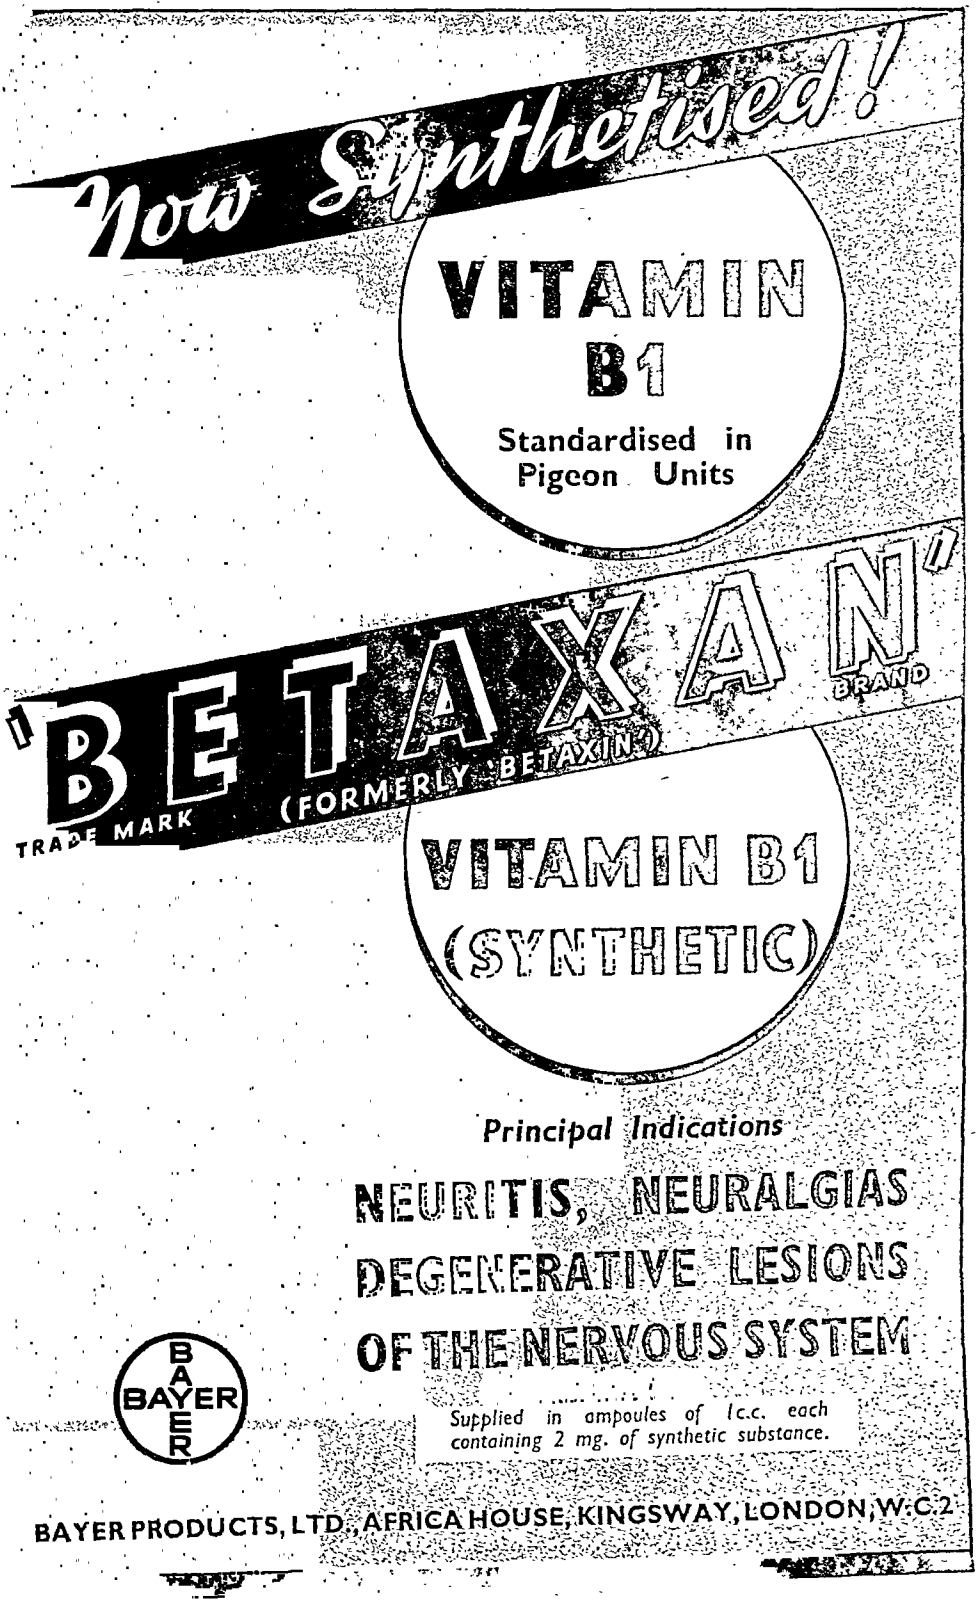
7 Promotes biliary drainage.

8 Is perfectly safe, even in large doses.

CHOLECYSTITIS

From information received :—

"I wish to state that the patient with cholecystitis to whom I administered Cystopurin has recovered."



"Cystopurin worked well in cure of cholecystitis and cleared up all symptoms and tenderness. There is no doubt it is good and far easier to take and absorb than any similar preparation."

"Oral administration of Cystopurin was shown to be preferable to —— and within 15 days of the commencement of daily treatment, the organisms entirely disappeared. ——, administered for a similar period, whilst freeing the urinary system of organisms, failed to influence the infection of the gall bladder and bile, which remained positive."

Supplied in bulk and in tubes of 20 tablets for dispensing purposes.

Synthetic Vitamins offered by 'Roche'

Roche Products Limited

have pleasure in announcing important additions to their series of vitamin preparations.

'Redoxon-Forte' Vitamin C

in 5 c.c. ampoules, each providing 500 mg., or 10,000 international vitamin C units, facilitates the parenteral administration of large doses of ascorbic acid. In boxes of 3 ampoules.

'Benerva' Vitamin B_1 Tablets

for oral administration, are now available in bottles of 20 and 100, each tablet containing 1 mg. aneurin (approx. 500 international vitamin B_1 units).

New 'Benerva' 1c.c. Ampoules

each containing 2 mg. synthetic aneurin, are now being offered to the medical profession. Though the concentration of the solution has been approximately doubled, prices remain the same. In boxes of 6, 12 and 50 ampoules. Further information on request.

Gonococcus Antitoxin
(P., D. & Co.)

A Specific Antitoxin for the Treatment of Gonorrhœa

The treatment of gonorrhœa with a specific antitoxin was described in the *British Medical Journal.* *

Although serum treatment in gonorrhœa is not new, previous work has been confined almost entirely to the use of antibacterial sera prepared by immunizing animals with cultures of the living organisms. Gonococcus Antitoxin is prepared by immunizing horses with injections of a soluble toxin of the gonococcus, using a method similar to that used in the preparation of Meningococcus Antitoxin.

Clinical trial of this Gonococcus Antitoxin has proved distinctly encouraging in acute and chronic cases—both complicated and uncomplicated—and has given results far superior to those obtained with other biological products hitherto available.

* "The Treatment of Gonorrhœa with a Specific Antitoxin." T. Anwyl-Davies, *B.M.J.*, Feb. 13, 1937, 1, 321.

Supplies of Gonococcus Antitoxin, prepared in the Biological Laboratories of Parke, Davis & Co., are available in vials of 30 c.c., and details relating to dosage accompany each package.

NEW ARMOUR LABORATORIES EQUIPPED FOR MOST MODERN METHODS OF POTENCY CONTROL

o *Air Conditioning Aids Control*

Armour's new laboratories have the finest, most up-to-date equipment. Temperature and humidity are perfectly controlled. The air in the laboratories is double-filtered.

o *Fresh Glands Important for Potency*

Huge batteries of vacuum dryers dehydrate the glands that frequently are so fresh they are still warm from animal heat. Liquid extracts in some cases are withdrawn only two hours after killing. They are then reduced under a 29-inch vacuum at low temperatures. Glass-lined tanks and glass-coated beaters are used.

In a comparative study Metaphen has been shown to be from 8.6 to 1,500 times more germicidal against *staphylococcus aureus* than five other commonly employed antiseptics, including mercuric chloride and tincture of iodine. Against other common organisms, Metaphen also demonstrated its marked superiority over all of the drugs tested. • Furthermore, Metaphen was found to be 10% more effective for surface skin and 87% more effective for deep skin disinfection than tincture of iodine. (*Annals of Surg., 93:587-597.*) • In addition to its great bactericidal power, Metaphen has other important advantages. It is non-toxic and non-irritating; does not coagulate serum or tissue albumins; and its solutions are stable when exposed to air. • Metaphen is supplied in a variety of forms, among which are: TINCTURE METAPHEN 1:300, a tinted, alcohol-acetone-aqueous solution prepared especially for use as a pre-operative skin disinfectant; as well as for all other conditions for which an extremely powerful but safe antiseptic tincture is indicated. • METAPHEN SOLUTION 1:500 is recommended for general use wherever a powerful germicidal action is desirable. Requests for professional literature will be welcomed.

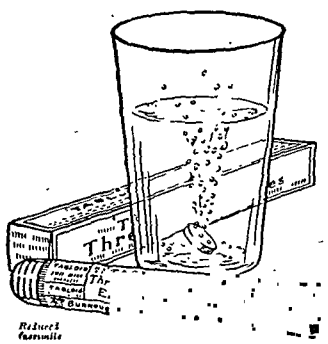
ANAHÆMIN B.D.H.

The anti-anæmic principle of liver

The administration of anahæmin in the treatment of pernicious anæmia results, within a few hours of the first injection, in a remarkable reticulocyte response which attains a maximum usually in five to six days; simultaneously, there is an appreciable rise in the red blood count which, in the majority of cases, continues rapidly after each injection reaching normal in five to six weeks.

A further satisfactory feature of anahæmin treatment is its effect on subjective symptoms: there is a return to the feeling of well-being and an increase in appetite; soreness of the tongue ceases, epigastric discomfort, vomiting and diarrhœa usually clear up within the first ten days, whilst paresthesia disappears in about two weeks.



Finally, treatment with Anahæmin B.D.H. therapy is not costly, even in a case requiring as much as 5 injections of 2 c.c. at intervals extending over a period of six to eight weeks the cost is less than 25s.; subsequent treatment by the injection of 2 c.c. per month costs approximately 5s. per injection.

Vitamin Concentrate or Natural Food?

The normal daily dosage of Bemax, i.e., ½-ounce, provides 200 International units of Vitamin B_1, which is from four to ten times as much as the recommended daily dosage of certain Vitamin B_1 "concentrates" advertised to the medical profession. If a higher intake is required, it is possible to supply as much as 600 to 800 units of Vitamin B_1 daily by the administration of three to four tablespoonfuls of Bemax, and this in an entirely natural form at only a fraction of the cost of concentrates.

The Vitamin B_1 potency of Bemax is assured by biological assay of every day's output.

BEMAX

Vitamin B_1—400 International Units per ounce.
Vitamin B_2—Flavine present B6—rich supply
Vitamin A—280 International Units (as Carotene).
Vitamin E—the richest natural source;
Phosphorus—330 mg. per ounce;
Magnesium—99 mg. per ounce;
Iron — 3 mg. per ounce;
Copper — 0·45 mg. per ounce.

Sterility and Habitual Abortion

The increasing use of Vitamin E for habitual abortion and sterility of dietary origin demands a wheat germ oil of proven high activity and of stable Vitamin value. Such an oil is available for the medical profession in Fertilol.

FERTILOL

A highly active source of Vitamin E.

BRITISH MEDICAL JOURNAL

LONDON SATURDAY JULY 10 1937

PARTIAL GASTRECTOMY

A REVIEW OF 320 CASES

BY

NORMAN C. LAKE, M.D., M.S., D.Sc., F.R.C.S.

Senior Surgeon, Charing Cross Hospital

In 1879 Pean performed the first gastrectomy; two years later Billroth reported the first successful case of pylorectomy and Wölfler did the first gastro-enterostomy, following the suggestion of Nicoladoni. Thus surgery entered into competition with medicine in the treatment of gastric lesions, and the intervening years have seen successive waves of opinion in favour of one or other form of treatment follow one another with such bewildering rapidity that it would take a medical Einstein to produce a formula which might lead to a conclusion unbiased by the particular mental standpoint of the observer.

In the past ten years there have been two peaks of medical interest—first, the reintroduction of intensive alkalinization, and recently, following the work of Aron, treatment by histidine. On each of these occasions the responsible surgeon and the conscientious practitioner must have felt at a complete loss to know what advice to give their patients, for who would dare advocate operative measures if the lesion could be permanently cured by simple dietetic and medicinal means? In the former instance the dilemma was solved by the passage of time, as surgeons found that most of the cases they were called upon to handle had already had a course of alkaline treatment. We are even now passing into a similar stage with regard to histidine, but its introduction is too recent to allow of any *ex cathedra* statement.

For this reason it seemed that the present was a suitable time to review the position of gastrectomy, but I was influenced in this decision by two other factors: the passing of the three hundredth case provided a convenient milestone and a sufficiency of material to reduce statistical errors to a comparatively small amount; in addition there was the desire to answer certain correspondence that followed the publication (Lake, 1928) of a much smaller series of cases in which a fairly high percentage of successful results was claimed. Thus Hurst (1928) commented: "Experience shows that the 'last' results—that is, after an interval of ten years or more instead of five years or less—would give a much greater number of unsatisfactory results." I have found it difficult to curb my impatience while waiting for the necessary interval to elapse which should provide the answer to this criticism, but I am now in a position to include a fair number of cases of over ten years' duration in this review. As will be seen later they fortunately do not support these gloomy prognostications.

The practitioner cannot be expected to be intensely interested in the technical details of the operation, however important to the surgeon they may be, and so in this article I shall limit the scope to a consideration of the effects of the operation, the results achieved, the risks involved, and such views of the aetiology of ulceration as have arisen from a study of the cases.

The total number of operations reviewed in the series is 320; so far as possible we have attempted to follow the cases for long periods and to carry out such post-operative investigations as appeared necessary or likely to provide information upon particular problems. The "follow-up" system has not been as efficient as I had hoped; in particular the industrial and financial crisis of 1932, with its consequent movements of the population, had a marked influence upon the continuity of the records. The number of cases followed for over five years is thus reduced; but this does not of course affect the immediate statistics relative to mortality, etc. A statistical study of the available figures has been made from many different angles, but only those will be given here which bear upon the particular points under consideration.

The lesions for which the operation has been performed may be divided into ulcers (gastric, duodenal, and pyloric), jejunal anastomotic ulcers, and carcinoma. The subdivision of ulcers into three instead of the more usual two types is a method which I have for long adopted, on account of the fact that in many large ulcers it is impossible to say on prima facie evidence where they arose. Commonly they are assumed to be duodenal, since gastric ulcers on the pyloric ring are held to be rare. I should have regarded this point as of but small significance had it not been that the mortality statistics quite unexpectedly showed it to be of some importance.

Lesions for which Partial Gastrectomy was Performed

Gastric ulcers	115
Pyloric ulcers	56
Duodenal ulcers	71
Jejunal ulcers	27
Carcinoma	51
	320

Such a list, however, fails to indicate that some of the gastric ulcer cases had progressed to hour-glass contraction (eleven cases); that some of the pyloric and duodenal ulcers had caused obstruction with dilatation of the

stomach (twelve cases); and that, apart from cases of jejunal ulcer, several had had previous gastric operations (perforation ten cases, gastro-enterostomy eight cases, local excision two cases). Nor does it show what, in my opinion, is a much more important feature, especially from the aetiological point of view—namely, that in a considerable proportion of instances the ulcers have been multiple.

I have previously pointed out that the surgeon whose practice includes but few gastrectomies is unlikely to be impressed by the frequency of multiple ulceration, since he has no opportunity of examining carefully the mucosa of the stomach but sees or feels merely the ulcer which is most active at the time of operation. Investigation of the parts removed by gastrectomy demonstrates that multiple ulceration has occurred in 40 per cent. of cases and that the combination of gastric and duodenal ulceration is by no means uncommon. Usually one ulcer only is active and the others are represented by thin scars, which give no indication of their presence on the exterior. By many the aetiology of duodenal and gastric ulceration is thought to be separate, but this view cannot be held if these findings are recognized. The only logical standpoint would seem to be either that one is dependent upon the other or that both are due to some common cause. While studying this series it has at times appeared that there might be some sequence of events, the duodenal ulcer with its higher acid curve preceding the gastric ulcer with its lower curve, but the observations have been of too vague a nature to enable any definite deductions to be drawn. Mills's (1917) studies of bodily habitus in relation to disease have led to the suggestion that the broad-chested, active, hypersthenic type, forceful both mentally and physically, is prone to the development of duodenal ulcer, while the asthenic individual tends to develop gastric ulcer. The theory is an intriguing one, and fits in well with modern ideas of physiological types, but there is little indication in this series that more than a small proportion of the cases conform to these types; many of the duodenal ulcers occurred in asthenic types. The theory is probably fundamentally correct, but the exigencies of modern civilization so complicate the issue that in practice it is of little value as a guide. Indeed the frequency with which gastric and duodenal ulcers are found in the same case shows that Mills's ideas can only be applied as a statistical approximation when large numbers are under consideration.

Aetiology

It would be as well here to consider one or two points in connexion with aetiology. There seems to be a general consensus of opinion among physicians and surgeons alike that eventually peptic ulceration will be treated by medicinal, or possibly by prophylactic, measures. This stage will not, however, be reached until more knowledge of the aetiological factors is obtained.

There are few manipulations to which the experimental animal can be subjected which do not produce a lesion of the gastric mucosa; injections of drugs, toxins, cytolysins, irritants, bacteria; excision of adrenals, thyroid, liver; interference with the nerve supply or with the central nervous system; changes in the blood supply or its composition; traumatization of the mucosa; production of pyloric stenosis, and other operative procedures. These methods, however, cause acute ulcers, which heal so rapidly as to make experimental observations difficult. Mann and Williamson (1923), by experimentally altering the normal relations of the alimentary canal, were able to produce chronic ulcers which were attended with the complications seen in human cases, notably haemorrhage and perforation. It must be stressed that great caution is necessary in drawing analogies between chronic ulceration in human beings and that in experimental animals, for in the latter profound metabolic changes must result from disturbing the normal relation of the stomach to the intestine. Following upon this work Aron (1933) conducted experiments which seemed to show that the duodenum supplied an important digestive element, the absence of which causes deprivation of the acid amines essential to life. The final stages in the digestion of proteins into simple amines is brought about not by the pancreatic juice but by the duodenal secretions. The amines which cannot be synthesized in the body are chiefly lysin, tryptophan, and histidine. Aron found that of these histidine could prevent ulceration in dogs subjected to the Mann-Williamson operation. Subsequent clinical trial with histidine has produced conflicting results. My own experience does not support the claim that histidine has a curative effect in cases of peptic ulceration. Many patients come to operation who have had several courses of this treatment. Apart from this, experimental work by Morton (1927) is in direct opposition to Aron's hypothesis that histidine protects the mucosa from attack by the gastric juice. Morton's researches, indeed, support the theory that the acid secretion is the most important single aetiological factor in peptic ulceration, combined with the trauma of forcibly ejected gastric contents—a theory suggested by Bland-Sutton many years ago. Experiences with cases of gastro-colic fistula, almost the equivalent in human cases of the Mann and Williamson experiment, are also in direct conflict with the theory. The part played by pepsin is not clear. But my own investigations suggest that the secretion of pepsin follows that of acid. As secretion of gastric juice is so dependent on psychological factors the interpretation of the reaction to a test meal is by no means free from fallacy. It is, however, generally agreed that the stomach in duodenal ulcer is hypertonic, hypermotile, and hypersecretory, and that the reverse is true in gastric ulcer—at all events in the chronic cases.

The link between these variations of secretion and motility in peptic ulceration would, it seems, be in the central nervous system: a theory that has experimental support. Cushing and others have shown that lesions in the hypothalamus are frequently associated with peptic ulceration, and it may be noted here that in this region is the controlling centre of the sympathetic system. It is well known that the progress of a peptic ulcer is affected by the emotional state of the patient, and that this is closely coupled with sympathetic activity. In this connexion it is undoubted that vasomotor effects also must play an important part in the aetiology of peptic ulceration.

It looks as if the riddle of peptic ulceration will ultimately be solved by reference to the autonomic control of the stomach and duodenum; and as the final transmission of nervous impulses is through a chemical intermediary, hormonic and chemical factors will come into the aetiological picture. Until these various problems have been solved and a rational medical regime made possible many cases of peptic ulceration will still be best treated by surgical measures.

Mortality of Partial Gastrectomy

It might be thought that the mortality rate of an operation would be the most definite and easily arrived at of all the statistics connected with its performance. A study of the published figures, however, soon reveals that it is

almost impossible to establish what may be considered a fair average general rate. The following list, for instance, indicates that the most careful scrutiny is needed before a mortality rate can be accepted.

Reporter	Cases	Mortality Percentage
Moynihan	164	1.6
Garnett Wright	62	4
Morley (Polya)	47	6
Bastianelli	137	1.5
Schwartz	*210*	*18*
von Haberer (Billroth II)	134	11
Finsterer	175	4
De Takats	226	5.4
St. Bart's: Ulcer	207	16.9
St. Bart's: Carcinoma	67	25.5
St. Bart's: combined		18.6

In the items in this list, where the total number of cases is less than one hundred, an error due to the small numbers may have crept in, for it is within my experience that as many as sixty consecutive cases may be performed with but two deaths, but that when the number expanded to a hundred the mortality figure approached the general average of a large series. For this reason the smaller numbers can be ignored. With numbers above a hundred, however, this error gets considerably smaller, and it will be conceded that when a surgeon has performed over a hundred operations of this type he can no longer be accounted a novice, so that the figures are not subject to the criticism that the mortality might be considerably lowered with further experience. Even so we find in this series the utmost discrepancy. For instance, Schwarz with an experience of 210 cases gives a mortality of 18 per cent., whereas Moynihan with 164 cases has a mortality of but 1.6 per cent. Now it is impossible to believe that the skill of two surgeons of very big experience in the operation can be as different as these figures would lead us to think, and it immediately becomes clear that we must look for some other explanation. Either the mortality rate is a selected one from which certain cases are excluded—and in this regard it is of interest to note that the term "primary mortality" has unfortunately crept into some statistics—or the type of case chosen for operation is very different in the two clinics. To exclude from the operating list cases which look to be difficult and are bad operative risks may be regarded as good surgical judgement, but unless we have complete knowledge of how the refused cases fared without operation we are not justified in lauding a low mortality dependent upon such exclusion. So we are left in doubt as to the real mortality, and this quandary will remain until all surgeons agree to publish a complete mortality list without any equivocation or the introduction of such qualifying terms as "primary mortality." For these reasons, in dealing with the present series, I give first of all the total mortality from all causes whatsoever up to a period of three months after the operation.

In this way certain conditions only remotely connected with the operation have been included; indeed, the number of deaths due to intercurrent disease, such as pulmonary tuberculosis and uraemia, gives a percentage actually higher than the lowest figure in the above list for the deaths from all causes. It is this in particular which has made me suspicious of accepting these figures without qualification, for it must surely fall equally to the lot of every surgeon, experienced and inexperienced, to have such sequelae after an extensive abdominal operation, often of necessity performed upon patients in poor general condition.

The total number of deaths in this series reckoned in this way is as follows:

	No. of Cases	No. of Deaths	Deaths per cent.
Ulcer cases	242	23	9.5
Anastomotic (jejunal) ulcers	27	4	14.8
Carcinoma	51	7	14.0
Total	320	34	10.6

There was no immediate mortality—that is, within twenty-four hours—in this series.

When the ulcer cases were further subdivided into their separate groups an interesting result was obtained. The mortality rates then were: gastric ulcer, 11.1 per cent.; duodenal ulcer, 11.4 per cent.; pyloric ulcer, 5.3 per cent. This considerable difference in the rates was unexpected and obviously needs explanation. The gastric and duodenal cases include the very difficult ones where the ulcer is close to the cardiac orifice or extends from the duodenum into the pancreas or liver. These are the cases which technically tax the surgeon's abilities to the maximum, and it is only to be expected that the mortality would be above the average. The ulcers in the vicinity of the pylorus, on the other hand, constitute the easier cases, usually quickly performed without difficulty. As a corollary it is obvious that the surgeon who so chooses his case as to include a large proportion of these pyloric ulcers will show a lower mortality than one whose choice is made on a wider basis.

Causes of Death

The causes of mortality are always worthy of study, for only in this way can technique be improved. Payne (1936) has recently published the results of the post-mortem findings at St. Bartholomew's Hospital. He found that the commonest causes of death were peritonitis and pneumonia (thirty-two and fifty-one cases), while shock and infection around the duodenal stump accounted for a further nine deaths.

In the present series the list is as follows:

Chest complications, including embolism but excluding tuberculosis	12
Pulmonary tuberculosis	2
Haemorrhage, internal and intraperitoneal	4
Leakage and peritonitis	6
Thyrotoxicosis	1
Uraemia	2
Influenza	1
Delayed shock	1
Rupture and resuture of wound	1
Intussusception, anastomosis into jejunum	1
Damage to mid-colic artery	1
Embolism from haemorrhoidal and internal iliac veins	2
	34

It will be seen that in five cases death was due to the lighting up of intercurrent disease (tuberculosis, uraemia, and thyrotoxicosis), while in three others (influenza and thrombosis of haemorrhoidal veins following enemata) it was only very indirectly connected with the operation. If these be excluded twenty-six operative deaths remain (8.1 per cent. for all the cases, or 7 per cent. for the ulcer cases. When the patient is otherwise healthy, therefore, this figure may be taken as a fair representation of the risk. If the surgeon chooses his cases to exclude the very high ulcers and the complicated duodenal ulcers this mortality may be halved, but it should not be overlooked

that the need for radical treatment is often greatest in the cases which would thus be excluded.

As in Payne's series the greatest risk is of pulmonary complications, with leakage and peritonitis coming second. The former are due more to the operative manipulations than to the anaesthetic used, and so it is not surprising to find that, although almost every known type of anaesthesia has been tried, there has been little variation in the mortality.

Results

The results in the ulcer cases must be considered to be very satisfactory; 198 cases have been followed for two years upwards, and of these only fifteen are unsatisfactory. A further investigation of the unsatisfactory cases showed that in over 50 per cent. (eight cases) a second condition was present to account for the symptoms; thus four cases had cholecystitis and two had colonic spasm. In the remainder the result is unsatisfactory on account of persistence of symptoms. Four were thought to have jejunal ulceration. In two of these exploration was undertaken; one revealed a small ulcer on the lesser curve proximal to the anastomosis and close to the cardia, the other had no abnormality of any sort. Three definite cases of jejunal (anastomotic) ulceration were operated upon elsewhere, one having perforated, and they are included in these results.

A further analysis indicates that on the whole the more severe the lesion the better the result. This is not to be explained on the psychological basis that the patient who has suffered intensely is inclined to exaggerate the quality of the relief afforded him, for in most instances there has been absolutely no pain or discomfort after the operation. It also appears that the percentage of unsatisfactory results is larger in the duodenal cases than in the gastric ulcers. Since, however, the majority of duodenal cases give satisfactory results, I believe the explanation of both this and the previous anomaly to be that a certain number of misdiagnosed cases are included, particularly cases where a small duodenal ulcer (probably completely inactive) is found at the operation, but the patient's symptoms are really due to other causes. With gastric ulcers, for obvious reasons, this error is less likely to arise. The inclusion of but a small number of such misdiagnosed cases in a series of this nature is sufficient to account for the less satisfactory results in the duodenal cases and for the better results in the larger and more obvious lesions.

A small group, otherwise satisfactory, complain of a transient feeling of biliousness before breakfast or of faintness after a heavy meal. These cases have been investigated without any physical abnormality being discovered. I cannot help thinking that such symptoms may be due to involvement of the gastric branches of the vagus in the stomach scar. But it must not be overlooked that an extensive operation often has a bad psychological effect. Some patients remain excessively apprehensive in the epigastric region for long periods, even permanently.

Effect on the Blood

The functions of the stomach as a haemopoietic agent are now well understood, and it might be expected in consequence that an anaemia, even a pernicious anaemia, would follow gastrectomy. In fact, for reasons that are not yet clear, there is very little change in the blood count. In this series a large number of post-operative blood counts have been undertaken, but there is no record of any case of pernicious anaemia as yet. Since twenty-seven of the cases are of ten to fifteen years' duration it might be expected that any reserves or store of haemopoietic substance would long since have been used up, if the pyloric end of the stomach is their only source. These are matters of medical interest; it is sufficient for the surgeon to know that experience shows that the dire results prognosticated ten years ago do not follow the operation. A mild microcytic anaemia does follow in some cases, but it is rarely severe enough to attract attention. An average of a large number of counts gave the following: red cells, 5,190,000; white cells, 9,390; haemoglobin, 95 per cent.; colour index, 0.88.

The Test Meal

The effect of the operation upon the test meal has been intensively studied. At the outset it must be realized that the performance of a test meal upon the post-gastrectomy case is associated with certain technical difficulties which render the results suspect. In this investigation every care was taken to ensure that the specimens were really obtained from the stomach stump and not from the intestine beyond.

Where a large Polya anastomosis has been performed there is almost always complete achlorhydria. With a restricted orifice there is in some cases a small amount of acid (15 degrees to 20 degrees) present in the one-hour specimen, but the general reduction of acidity is profound. Working on these cases Adler (1930) showed that even the completely achlorhydric cases retained the ability to respond to histamine stimulation, the test meal often showing over 20 degrees of acidity as a result of the injection. The same cases tested after a year or two had, however, lost the ability to respond. It was supposed that this might be attributed to a disuse suppression of the hormonic mechanism. Extracts prepared from the portion of stomach resected had no obvious effect.

Barium Meal

The radiographic results of the various types of gastrectomy were discussed by Shanks (1934) at the Bournemouth meeting of the British Medical Association. I cannot do better than quote from his paper:

> "Polya; Lake's Modification. This modification, judging by the radiographic appearance, controls the efflux of the gastric contents better than any other of the Polya type. In addition to preventing 'dumping' into the jejunum it renders reflux into the afferent loop very improbable. The gastric stump fills reasonably well in the erect position, and the stoma is clearly seen at the lower pole. The right border of the stump is formed by the remaining portion of the lesser curve and the sutured end of the stump above the stoma. This largely loses its initial angularity, and becomes more or less straightened out. At the junction of the two there is apt to remain a dimple, which must not be mistaken for a recurrent lesser curve ulcer."

Results in Carcinoma Cases

The most important conclusion reached in this group is that there appears to be no absolute relation between the size of the growth and the period of freedom from recurrence, provided that there is no widespread metastasis at the time of operation. In this series two cases of massive carcinoma, several inches in extent, are known to be free from recurrence for seven and nine years respectively, while another, in a young man, did not recur until six years had elapsed. The average duration of life after the performance of the operation has, however, been but two and a quarter years. The freedom from symptoms to within a short time before death has been gratifying, and makes it advisable to continue with the operation even when the presence of secondaries beyond the possibilities of removal is discovered.

Operation

It is not intended here to enter into a technical description of the various operative details, but a brief account of the operation I now perform is necessary. This has been evolved slowly over a period of years, and, although it gives a result which is not unlike that of the Finsterer operation, it was devised entirely independently, each separate modification being introduced in an attempt to avoid some observed defect or fallacy in the cases previously dealt with.

The anaesthetic is a high spinal percaine given by a modification of the Howard Jones method, which enables very small doses to be used. The majority of cases have no other anaesthetic, but gas-and-oxygen is not denied to those who are psychologically unfitted to remain conscious. In an early stage a local injection of percaine is given around the oesophageal orifice of the diaphragm to diminish the nauseating sensation produced by traction upon the vagus. The proximal line of division passes very obliquely across the stomach from as high up the lesser curve as is technically possible, to a point on the greater curve at the junction of the epiploic arteries. In the average case this means that about two-thirds of the stomach is removed. The distal section is placed across the duodenum about an inch beyond the pylorus, unless the presence of a large ulcer here makes a more distal division necessary. In a few cases a colossal ulcer here renders section of the duodenum impossible, and then the stomach may be cut across proximal to the pylorus, a modification advocated as a routine by Ogilvie. This modification is not to be recommended, however, for any other than the most difficult cases. Similarly the proximal line of section may, under exceptional circumstances, leave a very high lesser-curve ulcer and yet a good result may be obtained, but this is also a device to be adopted only in the face of great technical difficulties.

The anastomosis is a retrocolic one, the first coil of jejunum being passed through an aperture in the mesocolon, which is usually to the left of the midcolic artery. The proximal end of the coil is attached to the lesser curve so that the bowel descends across the cut end of the stomach. The stoma now made in the bowel is equal in length to but half, or less, of the width of the stomach and is situated at the lower end of the anastomosis. Suturing is continuous, but is performed in such a manner as to close the upper portion of the stomach aperture and to fix the uncut portion of the jejunal loop over the suture line. Extra sutures are placed at the lesser curve as a precautionary measure and to attach the anastomosis to the aperture in the mesocolon.

A small drain may be used in cases where there is much oozing or where penetration of the pancreas or liver by the ulcer has rendered cauterization of these organs necessary. Careful after-treatment is essential, and no operation of this type should be undertaken without preliminary transfusion if the haemoglobin percentage is under 60. With spinal anaesthesia shock is slight and patients usually leave the table with an extremely good pulse. The operation may take anything from thirty-five to seventy-five minutes, but while no time should be wasted it is a mistake to scamp any part of the operation for the sake of saving a few minutes.

Indications

The indications for the performance of a partial gastrectomy may be absolute or relative. Carcinoma in the absence of widespread secondaries falls into the first group, but this should also include cases of gross gastric ulceration. All other gastric ulcers which have not rapidly yielded to medical measures, and where the technical difficulties are not insuperable, should in my opinion be given the choice of a gastrectomy. Established duodenal ulcers without obstruction and with a high acid curve also form an indication, but those with pyloric obstruction and a low curve do so well with a gastro-enterostomy that it would be a mistake to subject them to the more risky operation. For anastomotic ulcers following gastro-enterostomy a gastrectomy is the only treatment likely to give permanent relief: some of the most gratifying results in this series come into this group.

Good surgical judgement, however, demands that many other factors connected with the patient's general condition be taken into consideration before the question of operation is finally decided.

Summary

1. Three hundred and twenty cases in which the operation of partial gastrectomy has been performed for gastric, duodenal, and anastomotic ulcers, and carcinoma are reviewed.

2. The after-history of the cases has been studied for periods up to fifteen years after operation.

3. Some aetiological ideas arising from the experiences of the cases are discussed.

4. The gross mortality from all causes was: ulcer cases, 9.5 per cent.; anastomotic ulcers, 14.8 per cent.; carcinoma, 14 per cent.

5. If an ulcer is situated in the pyloric region the mortality of the operation is but 5.3 per cent.

6. The commonest causes of post-operative death are lung complications and peritonitis.

7. The incidence of jejunal ulceration after partial gastrectomy is less than 2 per cent.

8. No cases of post-operative pernicious anaemia are recorded, but a microcytic anaemia of mild degree is occasionally seen.

9. The general permanent results in the ulcer cases are probably better than those obtained by any other method of treatment.

10. The average duration of life in the carcinoma cases after operation was two and a quarter years, but some patients with extensive growths lived for as long as seven and nine years.

11. The effects of the operation upon the test meal and the barium meal are described.

12. A brief account of the type of operation performed is given.

I should like to acknowledge my appreciation of the help I have received from Mr. D. Trevor, M.S., F.R.C.S., Mr. A. Higham, F.R.C.S., and Mr. T. Partridge, F.R.C.S., all registrars at Charing Cross Hospital, in the compilation of the numerous records from which the statistical results were derived.

TESTS FOR RENAL FUNCTION

BY

CHARLES S. D. DON, M.D., M.R.C.P.

Honorary Assistant Physician, Manchester Royal Infirmary; Honorary Physician, Salford Royal Hospital; Senior Consulting Physician, Crumpsall Municipal Hospital, Manchester

Three tests commonly employed for estimating renal function are the blood urea and urea clearance, the phenolphthalein test of Rountree and Geraghty (1910), and the maximum specific gravity of the urine. These tests have been carried out in sixty-four cases under my care in which it was thought that impairment of renal function might be present, and I have attempted to compare the results. The tests were made in three general hospitals by the laboratory staffs, in the course of their routine work. The patients investigated were suffering from acute glomerulonephritis (eight cases), chronic glomerulonephritis, benign hypertension, and hypertension with nephritis (malignant hypertension). This classification is at any rate descriptive of the types of cases. Oedema was present to a greater or lesser degree in all the cases of acute nephritis, but, apart from this, nephritic oedema was uncommon. Three patients had slight oedema, which was thought to be cardiac in origin.

Similar investigations have been reported by several other writers. The urea clearance test is usually regarded as the most accurate measure of renal function with the exception perhaps of the creatinine clearance test, with which it has been found to agree (Cope, 1931) if the original conditions mentioned by Addis—namely, diuresis and a raised blood urea—are adhered to; and Cope attributes the failure of Hok Lan Ong (1932) to demonstrate this parallelism to the fact that he did not observe these conditions. The normal value for the Van Slyke urea clearance (McIntosh, Möller, and Van Slyke, 1928) is 75 per cent. normal or over, and this was the clearance test used in this investigation. The phenolphthalein was given intravenously and the urine collected for two hours. The normal is 60 to 80 per cent. The fractional phenolphthalein test (Shaw, 1925; Chapman and Halsted, 1933) is said to be a better method. The maximum specific gravity test used was as described by Fishberg (1934), and is a modification of Volhard's (1918) test. The normal is 1020 and over. The modification introduced by Lashmet and Newburgh (1932) is claimed to be more sensitive, but it is more troublesome to carry out. One per cent. of dissolved protein in urine increases the specific gravity by 0.003, and an allowance must be made for this. It is recognized that in the presence of oedema the value of the maximum specific gravity test is diminished, and this must be borne in mind whenever it is being compared with other tests.

Analysis of the Cases

I have divided the sixty-four cases into two groups for the purpose of making a few comparisons between the renal function tests and the clinical signs presented by the patients. Group A (thirty-three cases) contains those cases in which one or more of the renal tests showed distinct impairment of function, and Group B (thirty-one cases) those in which no such impairment was demonstrated. Those in Group A were for the most part more seriously ill than those in Group B, but there was clinically no difference apart from the renal tests between some of the cases included in Group A and some in Group B. Twenty-nine of the thirty-three cases in Group A had, resting in bed, a systolic blood pressure of 180 mm. or over, as compared with seventeen of the thirty-one cases in Group B. Retinal changes, usually small haemorrhages, swelling of the disks, and white spots were observed in fourteen of the Group A cases and in only three of the Group B. Red blood cells were present in the urine of fifteen of the Group A cases, as compared with seven of the Group B. Blood counts were unfortunately only carried out when anaemia was thought to be present. There were twelve of the Group A patients in whom a haemoglobin value of under 80 per cent. was found and of the Group B patients only two, but these results are not strictly comparable. From the comparisons I have made and from a consideration of the symptoms of which the patients complained I concluded that renal function tests did, in many cases, give a good estimate of the patient's condition, but, on the other hand, often there was little correlation between the tests and the clinical examination.

Group A

Montgomery (1936) as a result of his investigations states that "sufficient emphasis has not been laid upon the necessity of interpreting [the urea clearance] results in relation to their blood urea concentration." In grouping the results of the renal function tests I have made use of the blood urea where possible. The sixty-four patients investigated were all conscious and able to give sufficient co-operation. Six had a blood urea of over 100 mg. per 100 c.cm. of blood, and in each case the urea clearance was under 16 per cent. and the phenolphthalein under 11 per cent.; five were chronic cases. In four of the six cases the maximum specific gravity was between 1010 and 1012; in the fifth case, a patient who was admitted with a blood urea of 135 mg. and who later died of uraemia with a blood urea of 216 mg., the maximum specific gravity was 1018. This last case was probably an acute nephritis, as the illness was said to be of short duration, marked oedema was present, and the urine was much diminished; but, on the other hand, the patient was 60 years of age and her systolic blood pressure was 205 mm. I did not detect any retinal changes. The sixth case was one of chronic nephritis passing very little urine, with a blood urea of 256 mg. and a maximum specific gravity of 1028. There was oedema of the lower limbs and in the back. This patient was able to concentrate the urine but was unable to secrete an adequate amount. In all six cases the blood pressure was over 200 mm., and the guaiac test or the microscopical examination of the urine showed the presence of blood.

There were twelve cases, two of acute nephritis, with a blood urea between 50 mg. and 100 mg. In ten of these, including the two cases of acute nephritis, the urea clearance was 35 per cent. or less. The urea clearances in the other two were 65 per cent. and 51 per cent., the blood ureas 50 mg. and 56 mg. Both were cases of chronic nephritis in which there was a little oedema thought to be cardiac in origin; the blood pressures were high and albuminuria was present. In one retinitis was found, and she has since died of cardiac failure. The maximum specific gravity was respectively 1014 and 1020, and the phenolphthalein 36 per cent. and 26 per cent. Clinically these two patients were as likely to have a clearance under 35 per cent. as many in whom this was found to be the case. The maximum specific gravity in this group of twelve cases was under 1015 in nine cases,

and in three it was 1020 or over: one of the latter was an acute nephritis with oedema, in another there was a slight degree of cardiac failure, and one patient died later of a stroke, but all three were cases in which probably there was some failure of renal function. The phenolphthalein results were below 60 per cent. in every case. It was evident that in most patients with a blood urea of 50 mg. or over the three tests gave readings below normal, but I was unable to make out any true parallelism between the extent to which the tests were depressed.

Of the remaining forty-six cases there were fifteen—two of acute nephritis—in which one or all of the tests showed some definite abnormality, in spite of the fact that the blood urea was in many cases normal and never as high as 50 mg. It is said that half the functioning kidney tissue can be removed before the blood urea shows any rise (MacKay and MacKay, 1927), and it was expected that there would be many patients with a normal blood urea in which other tests would demonstrate a loss of function. In ten of these the urea clearance was below normal, the exact figures varying between 32 per cent. and 65 per cent. In the other five the urea clearances were normal, the blood pressures were high, there was slight albuminuria but retinitis was absent, and there were no red blood cells in any of the urines when examined. In four of these five cases the maximum specific gravity was under 1020, and in two the phenolphthalein was below normal. There was slight oedema in two of these patients, which somewhat spoils the specific gravity test; but the other two had no oedema, the blood pressures were high, there was albuminuria, and it may well be that some degree of kidney damage was present. Of the fifteen cases, in four the maximum specific gravity was normal, and yet in these the urea clearance was decidedly low. In two of these red blood cells were present in the urine, another had retinitis, but the fourth had no retinitis and no red blood cells in the urine. In five of the fifteen cases the phenolphthalein was normal when the urea clearance showed a lowering of renal function. It will again be seen that the tests do not agree closely. It is clear that in many cases of renal disease any one test may fail to demonstrate loss of renal function and another show it to be present. Freyburg (1935) found among his cases of arteriosclerotic Bright's disease thirty-eight with impaired maximum specific gravity (Lashmet and Newburgh method, 1932) and only four with a lowered urea clearance. Perhaps his patients were not so ill as many in this investigation.

Group B

In the remaining thirty-one cases (Group B) the urea clearance, the maximum specific gravity, and the phenolphthalein were all normal or very nearly so. There were eight cases of acute nephritis, and in five of these the urea clearance and the phenolphthalein were reduced, in three to a marked degree as they were severe cases. In four of the eight cases the maximum specific gravity was 1020 or above that figure whenever taken throughout the illness. In two cases it was low, even on admission, and in two it was over 1020 on admission and dropped below this figure during the course of the illness. It was interesting to follow the improvement in renal function as the acute cases recovered. Cullen, Nelson, and Holmes (1935) found that in most cases of acute nephritis renal tests showed normal results one month after the cessation of acute symptoms. Alving and Van Slyke (1934) stated that in some cases of acute nephritis the maximum specific gravity failed to return to normal in spite of the fact that the clearances had reached normal figures; this was also observed by Freyburg (1935). Freyburg and Lashmet (1935) reported a case of mercuric chloride poisoning which recovered and in which the renal function tests were estimated frequently. The urea clearance was easily the most affected and dropped to 5 per cent., yet the non-protein nitrogen did not rise above 57 mg., and at the point when the clearance was 46 per cent. the maximum specific gravity was 1025 (Lashmet and Newburgh method, 1932) and the phenolphthalein 60 per cent.

Comparative Mortality in Groups A and B

Many cases have been followed up after leaving hospital. In Group A there have been during the past two years fourteen deaths, compared with three in Group B. Seven patients died of uraemia, two of apoplexy, three of cardiac failure, and two of pneumonia. In Group B two appeared to have died of cardiac failure and one of apoplexy. It was not possible to give an accurate prognosis from renal tests, as some cases went downhill faster than others and some severe ones maintained their position for a surprisingly long time. One chronic case when first seen had a blood urea of 46 mg., a clearance of 71 per cent., and a phenolphthalein reading of 35 per cent.; eleven months later the blood urea had risen to 120 mg. and the clearance had fallen to 14 per cent. In another case the clearance dropped in three months from 54 per cent. to 26 per cent. and the blood urea rose from 40 mg. to 75 mg. On the other hand many cases which had similar or worse renal readings when first seen are still alive and well. One case which I saw a year ago gave a phenolphthalein reading of 20 per cent., yet she is still alive, and the most recent test gave 36 per cent. The respective urea clearance results were 45 per cent. and 35 per cent.

Comparison of the Tests

In making a comparison one was struck by the fact that while on one occasion one test would seem to be the most sensitive, in another case it would seem to be the least sensitive. In many patients the maximum specific gravity appeared to be a very delicate test; in one case of uraemia, however, it gave a reading that was normal and in another nearly normal. The phenolphthalein often agreed with the urea clearance, but there were many occasions on which the one result was at variance with the other. In severe cases the agreement was good, both invariably showing marked reduction. The phenolphthalein is not regarded as a very sensitive test, yet in many cases, chiefly those with a high blood pressure, I found it to be apparently a delicate test, and low results were obtained more often than I expected. It was still more surprising to find that it sometimes showed an apparent loss of renal function before the urea clearance test. Lundsgaard and Möller (1925) believe that the dye output may be decreased in the presence of a high blood pressure, and this may account, in part at least, for the frequency of low readings in some of my cases. Chapman and Halsted (1933) state that they have observed cases of hypertension which showed depressed fractional phenolphthalein curves with few or no other signs of kidney disease, but have also seen normal curves in as many cases of hypertension in which there was no evidence of Bright's disease. Christian and O'Hare (1925) found that the two-hour phenolphthalein test did not demonstrate the earlier stages of kidney disease. MacKay and Rytand (1935) regard the phenolphthalein test as being of more value than the blood urea and the maximum specific gravity tests.

Chapman and Halsted (1933) believe the fifteen-minute phenolphthalein test to be more valuable than the two-hour test.

Elliot and Nuzum (1936) observed little correlation between the maximum specific gravity test, the phenolphthalein test, and the urea clearance test, and thought that what agreement there was between them was little better than could be expected as a chance occurrence. Riches and Robertson (1935) found the urea clearance to be a good index of renal function. Hutchison (1936) agrees with this view. Fowweather (1934) found it hard to establish even the normal clearance until he gave urea before the test. Van Slyke (1930) regards the urea clearance test as more accurate than the phenolphthalein.

None of these tests help us to give an accurate prognosis. Indeed, Elliot and Nuzum (1936) agree with Addis (1931) that none of the accepted methods of clinical examination can differentiate between patients likely to die in a year or two and those likely to live many years. Cope (1934) appears to hold a somewhat similar view. The rate at which renal function will depreciate varies from case to case, and Cope (1934) further states that even repeating the tests at intervals does not furnish information reliable enough to predict the course of the disease. This seems the more promising method. An increasing blood urea due to chronic nephritis means a bad prognosis, and, generally speaking, the higher the blood urea and the lower the results of renal function tests the sooner death will take place. The fact that tests of renal function are not all that one could wish for makes the ordinary clinical examination of the patient as important as ever it was.

Summary and Conclusions

Renal function tests have been carried out in sixty-four cases in which it was thought that kidney disease might be present. The tests used were the blood urea and urea clearance test, the maximum specific gravity test, and the phenolphthalein test. In the first group of thirty-three cases some loss of renal function was demonstrated, and the patients comprising this group were on the whole more incapacitated and death was commoner than among the second group of thirty-one cases, in which no loss of renal function was observed. Many of the cases were followed up after their discharge from hospital. On clinical grounds alone some of those included in the first group because of loss of renal function might have been included in the second group without causing the least surprise. The reverse is equally true.

With pronounced renal failure, as indicated by a high blood urea, the urea clearance and phenolphthalein tests showed marked depression of renal function, but this was not true of the maximum specific gravity. On two occasions it was normal, or nearly so, when the blood urea was over 100 mg. In both cases there was oedema and the patient was passing very little urine. The ability to secrete urine was at fault, but the ability to concentrate was normal. In some cases where renal function was apparently not nearly as severely impaired this test seemed to be very delicate, and the same may be said of the urea clearance test and the phenolphthalein test, each in some cases appearing to be the most sensitive. A surprising number of patients showed a lowered phenolphthalein excretion, but this may possibly be due to the fact that many had a high blood pressure. The lack of parallelism between the tests, especially in the lesser grades of renal damage, was most disappointing. None of them appear to be capable of enabling the clinician to give a very much more accurate prognosis than is possible from a knowledge of the blood urea alone. However, if any of the tests show marked loss of renal function in the absence of a raised blood urea it would probably be best to give a guarded prognosis. A re-examination of the patient in three months might help. Clinical examination will often furnish very valuable information, and must still be regarded as of the foremost importance.

To conclude, the failure of the tests to agree closely with one another suggests either that they are not completely reliable or that different renal functions are being measured.

The laboratory work was carried out by Dr. Loveday and Mr. Varley, M.Sc., A.I.C., of the Manchester Royal Infirmary, by Dr. Thomson of Salford Royal Hospital, and by Dr. Dawson and Dr. Smith of Crumpsall Municipal Hospital. It is a pleasure to thank them and the nursing staffs for their co-operation.

E. W. Twining (*Brit. J. Radiol.*, April, 1937, p. 332) describes an ingenious way of converting the ordinary Bucky couch into a tomograph. Tomography, planigraphy, and stratigraphy are names given to those methods of radiography which aim at the sharp radiographic representation of a selected layer of the patient's body, while all the other layers situated in front and behind the selected layer remain diffusely outlined. This is accomplished by moving the tube and film during the exposure in such a manner that the projections of all objects in the selected layer occupy the same positions on the film, while the projections of objects above and below that layer are blurred by movement. The apparatus described by the author consists of a lever mounted horizontally upon a vertical axis, which transmits the motion of the *x*-ray tube reciprocally to the Potter-Bucky carriage. Its length is equal to the focus-film distance. Its axis is variable along the length of the lever in order to allow the selection of any desired plane of the patient's body. The author describes and discusses experiments demonstrating the accuracy of his apparatus and its applications to clinical radiography.

THE CAUSES AND TREATMENT OF RETAINED PLACENTA*

BY

DAVID CURRIE, M.S., M.C.O.G., F.R.C.S.

Honorary Surgeon, Leeds Maternity Hospital

Retention of the placenta, with its common complication post-partum haemorrhage, is one of the disasters of child-bearing which even the most efficient ante-natal care cannot prevent. Before considering the causes of placental retention I would distinguish two entirely different conditions in which the placenta remains in the uterus: one is retained placenta, and the other is adherent placenta—much the more rare, having been reported in English journals on only two or three occasions.

Causes of Retention

Adherent placenta occurs when, for one reason or another, the spongy layer of the decidua is absent and the placenta finds direct attachment to the muscle wall (placenta accreta) or even invades the muscle wall (placenta increta). In neither of these instances will there be a line for cleavage, and so the placenta must adhere to the uterine wall. If this adhesion be complete there can be no danger of haemorrhage taking place, owing to the complete lack of placental separation. Repeated dilatation and curettage of the uterus and implantation over submucous fibroids have been suggested as predisposing causes, while incomplete adhesion may occur in the region of the uterine scars. The incidence of adherent placenta has been estimated to be from 1 in 6,000 to 1 in 40,000 births.

Retained placenta is a condition in which the placenta separates partially or completely, but because of some secondary complication (usually a mechanical one) is not expelled from the upper segment of the uterus. The commonest cause of placental retention is undoubtedly uterine inertia, and it is interesting to note that the use of forceps for delay in the second stage of labour often precedes a delay in the third stage. The presence of the placenta in the uterus is in itself a sufficient stimulus for the recurrence of pains in a short time after the delivery of the child. Weak pains are active enough to separate the placenta, but strong pains are necessary to strip off the adherent membranes and to push the placenta down the birth canal.

I believe that in most cases of delay in the third stage of labour the placenta is lying free in the uterine cavity suspended from the uterine wall by the membranes. This assertion is borne out at the operation of Caesarean section, when the placenta separates as soon as the child is delivered: on the other hand, its membranes are found to cling firmly to the uterine walls. This point requires emphasis, because it has an important bearing on the use of injection of the umbilical vein as a mode of treatment for retained placenta. Irregular contractions of the uterus (of which the best example is a contraction ring) may hold a placenta in the uterine cavity and act as another cause of delay in the third stage of labour. Such contractions follow interference—either internal interference during delivery, meddlesome interference with the fundus after the completion of the second stage, or, lastly, the injudicious use of pituitary extracts.

It was because the danger of over-zealous interference was realized that a rule for the conduct of the third stage of labour was introduced into the Leeds Maternity Hospital some years ago which forbade the touching of the uterus for twenty minutes after delivery of the child unless a free loss of blood merited fundal massage. Like all rules this one was bound to fail; in 1932 a patient bled to death owing to the filling up of her atonic uterus with blood, while no obvious outward signs of loss of blood were noted by the nurse in charge.

Nowadays a hand is placed above the fundus, not for the purpose of controlling it but rather to appreciate any changes which may take place in it: should it soften and rise in the abdomen, then gentle massage is applied to it in order to excite contractions of the uterus; should it harden and rise in the abdomen, then tests for the freedom of the after-birth are made. The estimation of the general condition of a recently delivered woman is a matter of considerable difficulty, for the amount of blood that she can lose without being upset varies greatly. The pulse rate may show an alteration of only five beats per minute after a loss of 1,700 c.cm. of blood. The blood pressure and pulse volume are much safer indices: a systolic blood pressure below 100 mm. suggests the need of salines, and below 80 mm. the need of a blood transfusion.

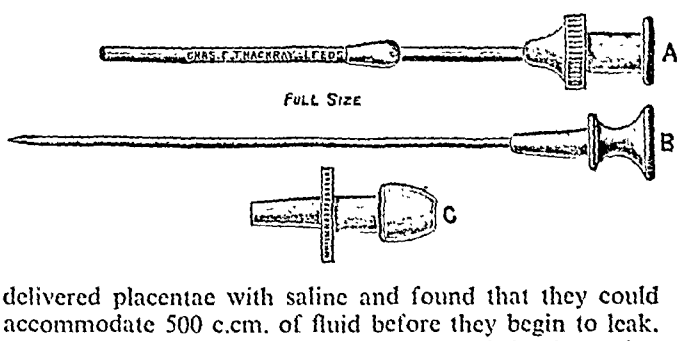
Certain mechanical factors may also act as causes of retention of the placenta. In placenta praevia the attachment of the placenta to the relatively inert lower segment and its consequent partial and delayed separation leads to post-partum as well as to ante-partum haemorrhage. Similarly, in hydramnios—quite apart from the possibility of associated uterine inertia—the placenta may be thin and may cover a large area, thus acting as a poor stimulus for uterine contractions. A patient is quite commonly received into the wards with a retained placenta and no bleeding in whom, after examination, the placenta is considered to be free in the uterine cavity, but its passage is prevented by a full urinary bladder: after catheterization expression is an easy matter. The presence of fibroids is another not uncommon mechanical cause of retained placenta; the retention may be due to the associated uterine inertia or the placenta may rest in a pocket formed from the uterine cavity which has been distorted by the fibroid.

Dangerous Methods of Removal

A placenta was said to be retained if it had remained in the uterus for two hours after the delivery of the child. This definition is adequate only in the absence of bleeding, for when there is post-partum haemorrhage it is imperative that the placenta be removed as soon as possible. At present the methods for the removal of the retained placenta in general use are Credé's manœuvre (at first without an anaesthetic and then with an anaesthetic), and, should this fail, manual removal. For some reason or other both yield better results in the hands of general practitioners than in those of the staffs of lying-in hospitals; nevertheless I feel that they are dangerous methods, especially that of manual removal.

During the past six years I have seen serious cases of shock, one case of complete inversion, one of ruptured uterus, and many of partial delivery with rupture of the placenta, all follow Credé's manœuvre and render it necessary for them to be sent to hospital. Manual removal of the placenta is one of the most fatal of surgical procedures, and one in every four cases in which it is used shows signs of uterine infection—according to the B.M.A. standard. Of eighty-four cases of manual removal recorded in Leeds between 1924 and 1930 thirty-eight were morbid and thirteen ended in death. The dangers of the

* Read to the Yorkshire Branch of the British Medical Association at its Annual Meeting in Scarborough, October, 1936.



operation are many, and include sepsis, shock, haemorrhage, and rupture of the uterus.

It is the fear of these complications that has encouraged the staffs of hospitals to avoid manual removal if possible, and it is to this delay that the high mortality rate from this procedure is attributable. Of thirteen deaths recorded in Leeds eleven occurred at or within a few hours of the operation and only two subsequently from sepsis. These figures suggest that the operation was delayed until it became an urgent necessity and the patients were *in extremis*. The frequent manual removals carried out by general practitioners without death supervening may be explained by the suggestion that they are done mainly soon after the delivery of the child (possibly in cases which hardly merit such intervention) and that they too are successful in avoiding the introduction of sepsis. In spite of this, however, two or three patients are admitted to hospital each year after manual removal has been performed, and death follows from one of the complications already mentioned.

Treatment by Injection

It is this difficulty of not knowing when the placenta should be removed manually that has made the introduction of the method of injecting the umbilical vein so welcome. This method was used in 1826 by Mojon, who employed cold acidulated water and thought that his results were obtained on account of the low temperature. Jarcho in 1928 described two cases in which, after the injection of 250 c.cm. of saline into the umbilical vein, the placenta was expelled. He surmised that a retroplacental hydroma was formed which separated the placenta. It was this memorandum that suggested our starting work on the injection method, the technique of which may be outlined as follows.

The umbilical cord is cleansed with spirit, the trocar and cannula is inserted into the umbilical vein about eight inches from the vulva, and held in place with a cord ligature; 450 c.cm. of sterile saline at blood heat are then injected as rapidly as possible by means of a Higginson's syringe. The uterus rises in the abdomen, contractions occur, and the placenta is separated; in many cases it is expelled spontaneously. I injected a hundred freshly

delivered placentae with saline and found that they could accommodate 500 c.cm. of fluid before they begin to leak. This finding invalidates Jarcho's theory of the formation of a retroplacental hydroma. Doubtless the true explanation lies in the fact that on injection the placenta increases until it is nearly twice its original bulk, packs the uterus, stops the bleeding, and in most cases elicits contractions forcible enough to push the placenta into the vagina and to strip off the membranes from the wall of the uterus.

After the completion of the injection tests are made for the freedom of the placenta. If these tests show that the placenta is in the lower uterine segment or in the vaginal vault the fundus is massaged and the placenta is expressed. If, on the other hand, the tests show that the placenta is still in the upper part of the uterine cavity the patient must not be disturbed. The uterus has been packed by the distended placenta and bleeding ceases; further solution may be injected if bleeding recurs, and eventually, as the patient's condition improves, the uterus will regain its tone and the placenta can be expressed.

Advantages of the Method

The injection method has the advantage of simplicity in that it requires little surgical technique. Moreover, the umbilical vein is the largest vessel in the cord and the needle can be easily introduced. Water which has been recently boiled may be employed, and after the injection has been completed the cannula may be plugged by reinserting the trocar. It is advisable to insert the cannula into the vein as far away from the vulva as possible in order to preserve a long length of cord lest further injections be found necessary.

Surprise may be felt that such a convenient way of releasing the placenta fell into disuse. Its disrepute resulted from the use of non-sterile acidulated water, causing some patients to become septic; from the statement made by a well-known obstetric surgeon in Germany (Koerting, 1925), where the method was commonly employed, that it was of no value in cases of haemorrhage; and from the fact that unless the fluid is injected quickly no rapid change in the bulk of the uterine content is obtained and the resultant uterine contractions are weak. Consequently the use of glycerin as the injection fluid is not likely to yield good results, because such a viscid fluid cannot be injected quickly.

After the introduction of the injection treatment of retained placenta the need for manual removal immediately fell from twenty-five to one or two a year, and that method was used in cases where the cord was macerated or absent. In the Leeds records up to the end of the year 1935 the umbilical cord had been injected on 186 occasions, mainly for retained placenta, with or without post-partum haemorrhage; of these only two cases ended fatally and eight were reported morbid. One of the deaths occurred after admission in a moribund condition, and the other was that of a patient with advanced heart disease. The septic cases all followed instrumental delivery. In comparing these figures with those of manual removal we find that the death rate is 1.6 per cent. against 15.4 per cent., and the morbidity rate 8 per cent. against 45.2 per cent.

Additional uses to which the injection of the umbilical vein can be put include prophylaxis against post-partum haemorrhage (it is our custom to inject the vein if the patient has lost 600 c.cm. of blood without delivery of the placenta) as a precaution in cases of placenta praevia immediately after the delivery of the child, and as a means of clearing the field before suturing episiotomy wounds or tears accompanying a difficult instrumental delivery.

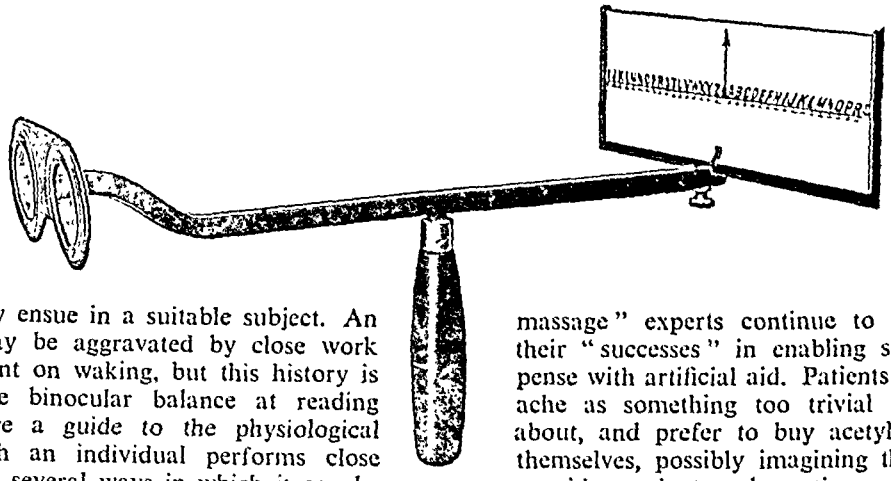
R. Drenkhahn (*Med. Welt*, March 20, 1937, p. 394), on purely theoretical grounds, arrives at the conclusion that atropine in small doses causes a relaxation of the sphincter of the portio vaginalis of the uterus, while it has no effect, or possibly a slight stimulating effect, on the muscles of the body of the uterus. It should be useful in over-activity and tetanus of the uterus, but it is relatively useless in normal labour, in which the hypophyseal extracts are far more effective.

In a child, of course, this may lead to strabismus, transient and easily remediable at first, but if it be neglected even for a few weeks the child adapts himself to monocular vision and intractable amblyopia is liable to result.



Latent Strabismus

The established habit of binocular vision in adults prevents this excess of convergence from becoming apparent as a frank squint, but the effort of maintaining a satisfactory balance imposes a strain reflected in several ways. Common among them is the inability of students, otherwise capable, to concentrate upon uninteresting textbooks, a tendency of the aged to fall asleep over their newspapers, while those who persevere in close work in spite of their difficulty are very liable to experience headache.

If, in the course of an operation for squint under efficient local anaesthesia, traction by a squint hook is exerted upon an internal rectus muscle, one is struck by the fact that the discomfort experienced by the patient is described as headache.

The Use of the Convergiometer

The headache due to latent squint at close range is commonly situated at the root of the nose or across the brow, and attacks of characteristic migraine or of migrainoid type may ensue in a suitable subject. An ocular headache may be aggravated by close work and is seldom present on waking, but this history is not invariable. The binocular balance at reading distance is therefore a guide to the physiological comfort with which an individual performs close work, and there are several ways in which it can be tested. A practicable one is by the use of the convergiometer. Its principles of construction were devised by the late Mr. Maddox many years ago, and they reflect his ingenuity in their simplicity. This very simplicity and the consequently inexpensive nature of the instrument may have prejudiced wider acceptance, for the wholesale manufacturers state that the demand has always been moderate. I am indebted to them (The Ellis Optical Company of Croydon) for the loan of the block.

A card bearing an arrow with a line of letters is seen through the eyepiece as two, one image being displaced upwards by a prism before the left eye and a second identical image being displaced downwards by a prism before the right eye. For the purpose of this test the patient wears reading glasses if he has them. A square of small newsprint pasted across the shaft of the arrow assists by concentrating the patient's accommodation on the card. If the lower arrow—that is, the one belonging to the right eye—points to the *left* of the upper arrow to some letter in the latter part of the alphabet all is reasonably well, for the internal recti have powers of convergence independently of those inseparable from accommodation and can make up for any lack in this respect. If, however, the lower arrow wavers even a little towards A on the right of the upper arrow—and certainly if it reaches this letter or beyond—the eye muscles are under a constant demand to exert a divergence (for which they have little capacity) up to and sometimes beyond the limit of comfort and almost of possibility, leading to headaches as the expression of such effort.

Correction by Eye-glasses

Great and perhaps undue stress has been laid upon small astigmatic errors as the cause of headache. The relief of headache by correction of such errors is often due to the restoration of normal muscle balance by adequate glasses. If a patient has bought for himself a pair of spectacles, estimated, fitted, and casually centred *without correction of any muscle imbalance present, it is* possible, should headaches persist, that he and his doctor will pursue their research for the cause elsewhere, and may part ultimately with expressions of mutual dissatisfaction. There is still some prejudice against the use of spectacles, and it has been suggested that numbers of people are wearing glasses unnecessarily as a result of commercial advertising campaigns. As long as all those not certifiably insane are assumed to be able, by exercise of their reason, to discriminate in such matters without expert guidance this possibility must exist, and the "eye massage" experts continue to reap the reward of their "successes" in enabling such patients to dispense with artificial aid. Patients often regard a headache as something too trivial to consult a doctor about, and prefer to buy acetylsalicylic acid tablets themselves, possibly imagining that their doctor can provide no better alternative.

Conclusion

The appreciation of pain and pleasure is very much a matter of temperament. Headaches are seldom incapacitating to those who may be described as "human vegetables," and when a phlegmatic, healthy individual complains diffidently of constant or frequent pains in the head investigation should be very thoroughly carried out. It must be a part of the treatment of the temperamental and neurotic patient to reduce to its true proportion each new symptom, whether of headache or any other kind; but to be effective this devaluation must follow such investigation as may be possible to exclude any real cause for such symptoms.

The use of test type and ophthalmoscope, and a rapid investigation of the lateral eye muscle balance at reading distance, will not reveal or exclude every ocular cause of headache, but they represent a simple, rapid, and sound method of ensuring as far as may be possible that appropriate ophthalmic attention is quickly given to those more obviously needing it, while others are referred for investigation to those quarters from which they are more likely to benefit.

LUMINAL AND PROMINAL IN EPILEPSY

A COMPARATIVE STUDY

BY

C. GUY MILLMAN, M.R.C.S., L.R.C.P.

Deputy Medical Superintendent, Cell Barnes Colony

The results recorded in this paper represent an attempt to compare the efficiency of luminal* with that of the more recently introduced barbiturate prominal* in the treatment of epilepsy.

In view of the satisfactory experience with the use of the latter drug reported by Heyde (1932) and other Continental workers, prominal was substituted for luminal in the routine treatment of epilepsy in this colony for mental defectives. The results in the aggregate were so striking as to warrant closer scrutiny and analysis. The comparison is therefore made in retrospect from a survey of routine clinical records, and not according to a predetermined method. The major and minor fits in all epileptic patients had been recorded on four-hourly charts.

Method of Substitution

The change from luminal to prominal, which was started throughout the colony on the same date, was made gradually by the method recommended by Blum (1932). Thus for the first four days one-third of the total luminal dosage was substituted by one and a half times that amount of prominal, for the second four days two-thirds were similarly substituted, and on the ninth day the whole luminal dose was replaced by a dose of prominal 50 per cent. greater. During and immediately after the change to prominal the majority of patients showed some increase in the number and severity of fits, but in no case did this assume alarming proportions. Subsequently dosage was adjusted to suit individual cases.

Choice of Cases

For the purpose of comparison only those cases known to have been under treatment with a suitably adjusted dose of luminal for some considerable time have been chosen. These cases had thus been observed for varying numbers of weeks immediately before the change to prominal. It should be pointed out that in every case the dose of luminal had been adjusted to a level low enough to avoid hypnotic effects. No case under any other form of treatment has been included.

Although no reference to the subject has been found in the literature, there appears to be some clinical evidence in support of the view that the incidence of epileptic fits and the mood of the patients bear some relation to atmospheric conditions. In order to minimize any error that might have arisen from seasonal variation those cases still available were observed for a similar period of weeks one year later, by which time the effect of prominal had long since become established.

From the records of eighty-two epileptic patients the number available as satisfying the above criteria is thirty-nine. The results in these cases are given in the following table.

Effect on Incidence of Fits

While there is considerable individual variation in results the mean weekly fit rate is reduced as follows: under luminal, 2.621; under prominal, 0.923. Hence the average weekly fit rate per patient on prominal treatment is 1.698 lower than, or roughly one-third of, the rate on luminal. The question now arises, Could such a difference be due to chance? The necessary statistical test was applied, and it was found that the odds are nearly 300 to 1 against such a result being a mere chance event. The reduction in the total number of fits since the

* The luminal and the prominal used in this study were obtained from Bayer Products Ltd.

In the last column: +=Improvement; —=Retrogression; O=Condition stationary; a blank signifies no abnormal behaviour attributable to epilepsy.

change over to prominal is such that to see a patient in a fit in the colony grounds is now a rare occurrence, although a degree of freedom which is perhaps unusual is allowed to the majority of patients.

The individual variations in results are shown in Table II, which is based on the figures set out in Table I. This shows in ascending order of magnitude the number of major and minor fits which might be expected to occur in each patient under prominal treatment if, during an equal period of luminal treatment, he had experienced a hundred fits.

TABLE II.—*Calculated Number of "Prominal Fits," in each Case, per Hundred "Luminal Fits" (Average = 41)*

Case No.	No. of Fits	Case No.	No. of Fits
2	Nil	37	32.8
14	"	27	38.7
16	"	6	38.9
23	"	8	41.4
35	"	11	41.7
1	2.6	36	42.9
25	2.8	18	43.1
5	4.8	7	46.1
17	10.5	30	49.0
32	10.5	33	55.5
15	11.1	34	63.6
3	12.5	28	65.1
24	13.8	10	67.2
29	15.7	9	72.0
21	16.7	19	75.0
22	16.7	13	84.6
4	18.6	12	87.5
20	21.6	38	137.5
26	25.0	39	314.3
31	32.0		

Thus there is a considerable improvement in the majority of cases, while two cases show deterioration and a few show improvement of little or no significance. No common factor has been noted which would lead one to expect a particular type of response.

Effect on Behaviour

It will be seen from the last column of Table I that of twenty-seven cases showing examples of abnormal behaviour considered to be epileptic equivalents, nineteen were improved by prominal, one became worse, and seven showed no change. Again there is no obvious factor underlying a particular response.

Results in Typical Cases

As the effects of prominal on epileptics of relatively normal mentality will be of more general interest feeble-minded cases (rather than idiots or imbeciles) will be described in greater detail. Those nearest the middle and the extremes of the scale as shown in Table II are taken as typical of the varying forms of response.

Case 5.—This patient was a feeble-minded woman aged 29, in good physical condition. On luminal, 2 grains twice daily, her fits averaged nearly ten per week (approximately one out of every nine being major fits). She lacked initiative and was frequently troublesome; her epilepsy seriously interfered with her work and recreation. On prominal, 3 grains twice daily, she had an average of one fit a fortnight during the period under review. Since then the fit incidence has decreased and she has had no fit for eighteen months. She is now much brighter mentally, and is able to do useful work and to take part in Guiding and other colony activities.

Case 22.—This case was that of a feeble-minded man of 27, simple in manner, in good health apart from some chronic bronchitis. On 1 grain of luminal daily he was often excitable and quarrelsome, and needed much supervision when following his simple occupation. His fits, of which approximately two-fifths were major, averaged nearly two a week. During the corresponding period of prominal, 2 grains twice daily, he had no major fits, and the minor fits averaged one in about three weeks. His conduct was improved and his usefulness increased. Subsequent increase of dosage to 3 grains twice daily has not resulted in any further improvement.

Case 12.—This patient was a feeble-minded man of 33, in good health. He was simple and confused in manner; with a dose of luminal exceeding 1/2 grain daily his confusion increased and his capacity for employment was negligible. On this small dose of luminal his fits, mostly major, averaged about one a week and he became troublesome and resistive at times. He tolerates a prominal dosage of 3 grains three times a day. This produces little effect upon the incidence of fits, but his conduct is greatly improved and he is able and willing to work in the kitchen garden.

Dosage and Tolerance

Many adults in good physical health have received prominal, 3 grains three times a day, for over two years without ill effect. The dose for children has been estimated by the usual formula $\frac{\text{age}}{\text{age} + 12}$, which appears to be entirely satisfactory.

In a few adults of poor physique, particularly when they are constipated, some degree of drowsiness has been observed when the maximum dose of 9 grains daily has been given. In such cases appropriate measures are taken to deal with the constipation, and prominal is withheld for three days, after which the full dose is again established. In view of the well-known intolerance to barbiturates in cases of renal disease, the urine is examined in all cases showing drowsiness, in order to exclude the possibility of incipient uraemia.

While prominal appears to be the drug of choice for the majority of cases, luminal may be used in preference in those cases of low mental grade in which some hypnotic effect is not undesirable and in which the effect of prominal is disappointing.

Summary

A comparison of the efficacy of prominal and luminal in the treatment of epilepsy is made by examining the routine records of all epileptic patients in a colony for mental defectives; each case has been observed during similar periods on the respective drugs.

The principles by which cases were selected are described, and thirty-nine statistically admissible cases are recorded in tabular form.

The results are considered collectively and individually with reference to both incidence of fits and behaviour. The total number of fits under prominal treatment is shown to be approximately one-third of the number during a similar period under luminal therapy, and a beneficial effect on non-convulsive manifestations is found in a large proportion of cases.

Tolerance is discussed, and a dose of 3 grains of prominal three times a day is shown to be satisfactory over long periods in adults.

I am indebted to Dr. Noel H. M. Burke, medical superintendent, Cell Barnes Colony, for permission to publish the results of this investigation. My thanks are also due to Professor Major Greenwood and his staff for kindly looking over the results.

PROMINAL IN THE TREATMENT OF EPILEPSY

BY

C. J. HENDERSON, M.B.
Medical Superintendent, Royal Albert Institution, Lancaster

The results of the treatment of epilepsy by prominal in mental hospitals recorded in the *British Medical Journal* by Dr. L. G. Millar Page (March 14, 1936, p. 531) and Dr. Leonard Barber (March 28, 1936, p. 666) were so encouraging that it was decided to try the effect of prominal on the mentally defective patients in this institution who had had the greatest number of fits during 1935. The fourteen patients chosen were having various forms of treatment by drugs and diet, etc. Some had had luminal without any marked improvement, but were not receiving it at the time the use of prominal was begun. On April 1, 1936, every other kind of treatment was stopped, and in only one case has anything except prominal been given since then. One of the fourteen cases was discharged to another institution after six months, so that the figures below relate to thirteen only. All the thirteen patients had been having epileptic fits regularly for from three to twenty years, and the number of fits recorded in the preceding twelve months was rather more than in previous years.

The reduction in the number of fits in the first three weeks of treatment with prominal (twenty-eight against 124 in the corresponding period in 1935) was so remarkable that it was decided to keep exact records of these cases for the next twelve months. This has been most carefully done by Mr. D. D. Steadman, surgery attendant.

Case No.	Number of Fits: April 1 to March 31		Decrease in Number of Fits
	(Bromide, etc.) 1935–6	(Prominal) 1936–7	
1	581	107	474
2	327	137	190
3	191	55	136
4	150	112	38
5	122	2	120
6	93	93	—
7	69	67	2
8	72	11	61
9	62	7	55
10	109	45	64
11	51	13	38
12	263	42	221
13	38	5	33
Total	2,128	696	1,432

It will be seen that there was a reduction of just over two-thirds (67.3 per cent.) in the number of fits in twelve months.

To begin with, each patient was given 9 grains of prominal a day—that is, one tablet three times a day—but in nearly every instance this was found to be too much and had to be reduced—in some cases on April 2 and in the rest on April 4. The main symptom of overdosage was drowsiness, and the dose was reduced to 6 grains daily. In Cases 2, 4, 6, 7, and 10 the daily dose was further reduced to 3 grains, but after a few days was restored to 6 grains.

Case No. 1.—For several years this patient was quite useless and under constant observation owing to the frequency and severity of fits. Is now doing housework, and fits are less severe as well as less frequent.

Case No. 9.—Fits reduced from sixty-two to seven. Much brighter mentally.

Case No. 12.—Had been bedridden for six months owing to severity of fits. Is now up and back at school.

Case No. 8.—Has been at work regularly lately (shoemaker).

Cases 2, 3, and 4.—Not much improved mentally.

Cases 5 and 13.—Low-grade imbeciles, but much more lively and cheerful.

Case No. 10.—Physically improved. This patient has had an average of 118 fits a year for the last twenty years. (In 1900 he had craniectomy operation for epilepsy, without any improvement.)

Case No. 11.—Little change. This patient is 67 years old.

Case No. 6.—Has not benefited; 9 grains daily reduces the number of fits, but produces drowsiness to such an extent that he is unable to walk; 6 grains daily has no more effect on the number of fits or their severity than bromides.

Case No. 7.—This is the only patient who has had any other treatment besides prominal. Up to the week ending November 14 he had had nearly 50 per cent. less fits than the previous year. During the week ending November 21 he had forty fits in three days, and was given bromide and chloral hydrate by mouth and by rectum in addition to prominal. Since then he has had only nine fits, against twenty-nine in the corresponding period of 1935. He takes 3 grains of prominal daily.

During the time these patients have been undergoing this treatment there has been no alimentary disturbance. Nothing abnormal has been found in the urine, nor has the blood pressure been found to vary to any great extent. So far there has been no indication that the drug is losing its efficacy. The treatment is being continued, and other cases of epilepsy are receiving prominal. All those treated were suffering from *grand mal* only. Prominal has not been found to have any effect on the few cases of *petit mal* on which it has been tried.

J. J. C. P. A. Roovers (*Nederl. Tijdschr. Geneesk.*, May 22, 1937, p. 2346) records the case of a girl, aged 5 years, who suffered from generalized calcinosis. The Wassermann, Müller, and Kahn reactions in the blood were negative. She was given 3 grammes of sodium citrate a day by mouth and calcium intravenously. In three weeks after the treatment was begun the calcium content of the blood rose from 11.5 mg. to 20 mg. per 100 c.cm. of blood, and the phosphorus content from 4.7 mg. to 10.8 mg. per 100 c.cm. Slow but steady improvement followed. The calcium nodules subsided, the contractures disappeared, as did also the limitation of movements in the joints, and practically complete recovery took place.

Clinical Memoranda

Lymphosarcoma with Perforation of Gastric and Intestinal New Growth

It must be exceptional for a case of lymphosarcoma to present perforation of both gastric and intestinal new growth. I do not know of a recorded case. Ewing (1928), in a detailed account of lymphosarcoma, mentioned the possibility of intestinal perforation, and cases of the latter have been reported, though infrequently—for example, by Whitaker and Fisher (1934). Gastric perforation in lymphosarcoma would seem to be even rarer, for no record has been found in the literature consulted.* The following case, presenting both complications, is therefore of interest.

CASE RECORD

A. B., a male 34 years old, was admitted to St. Stephen's Hospital (L.C.C.) on November 13, 1936, presenting bilateral glandular enlargements in the following regions: submental, pre-auricular, lateral cervical, supraclavicular, inguinal, femoral, and axillary. The patient had first noticed swellings in the groins two years previously, and he said that the other swellings had been present for two months. Examination showed that, in addition, the right posterior part of the tongue was thickened, ulcerated, and fixed to the adjacent faucial tissue. There was gross oedema of the left leg, the lumbar region, and the penis, and dilated veins coursed over the right upper chest wall anteriorly. The liver was moderately enlarged, but the spleen was not palpable. The face was pale, the expression strained, and the cervical swellings gave a square outline to the face. The pulse rate was 116 per minute and the temperature normal. Examination was negative in other respects, as were also ophthalmoscopic and urinary examinations and the Wassermann reaction.

Two days after admission he complained of the onset of acute lower abdominal pain and nausea. The temperature was 99° F., the pulse rate 120 per minute. There was neither abdominal tenderness nor rigidity. The next day (November 16) he was markedly breathless; the abdomen was tense and ascites was present, but the abdominal pain had subsided. He died on November 18, five days after admission.

At necropsy the identity of the glandular masses enumerated above was confirmed. The right posterior part of the tongue was infiltrated with hard new growth and attached to the fauces. There was a large mass of intensely white glands in the mid-mediastinal region, matted together, and less extensive enlargement of the glands about the aorta; here the glands were black. The abdomen contained several pints of yellow turbid fluid. The liver showed perihepatitis and fatty degeneration. The spleen was moderately enlarged and unduly soft. There was malignant ulceration of the lower part of the posterior wall of the stomach, which had perforated. Further, there was extensive lymphosarcomatous involvement of the ileum, with perforation of an area of malignant ulceration which was close to a Meckel's diverticulum.

PATHOLOGICAL REPORT

The following report was made by Dr. G. W. Goodhart:

Stomach.—The tumour consists of rather large mononuclear cells with a fine fibrillar stroma. It has completely replaced the mucous membrane over a large area, and is here largely necrotic. In places there is a dense fibrous tissue reaction with atheroma of the arteries.

Intestine.—The main mass of the growth is in the submucosa, with extensive ulceration of the mucous membrane; the whole area is infiltrated, and in the neighbourhood of the perforation the muscular wall is entirely replaced by growth, with a thick layer of fibrinous exudate on the peritoneal surface. The lymphosarcoma cells are of the same type as those seen in the stomach.

Mediastinal Glands.—The normal structure of the gland is destroyed, and is replaced by large mononuclear cells in a meshwork of fine fibrin.

Spleen.—The histological picture is one of general infiltration by lymphosarcoma cells.

Liver.—No growth seen; severe fatty degeneration.

It is a pleasure to thank Dr. G. W. Goodhart, pathologist of the Group Laboratory, St. Mary Abbots L.C.C. Hospital, for his report and his interest; also Dr. D. S. Sandiland, medical superintendent of St. Stephen's L.C.C. Hospital, and Sir Frederick Menzies, medical officer of health of the London County Council, for permission to publish this case.

ELI DAVIS, M.Sc., M.D.,
Assistant Medical Officer (Grade I).

Carcinoma of Rectum in a Girl of Twenty

The case described by Mr. R. Rutherford on page 860 of the issue of the *Journal* for April 24, 1937, invites comparison.

In 1931 an unmarried girl of 20 began to feel pain on defaecation and passed blood and mucus in the stools. This continued until April, 1933, when she sought advice and was sent to hospital by her doctor.

The patient was pale, thin, and weak. Rectal examination revealed an ulcerated friable growth involving three-quarters of the circumference of the ampulla and about four inches in length, extending downwards to within 1½ inches of the anus. Rectal mobility could not be elicited. Microscopically the growth was seen to be an adenocarcinoma, the tumour cells being of columnar type with little tendency to anaplasia. Long radium needles (0.8 mm. Pt) were inserted per rectum in a cylindrical distribution in the plane of the tumour bed, and three months later a small area of residual growth was re-irradiated, using a few underscreened radon seeds (0.3 mm. Pt).

After an interval of three months digital and sigmoidoscopic examination under anaesthesia was carried out. An elastic transverse ridge causing a minor degree of stenosis was palpable through smooth intact mucosa. There was no ulceration or sign of residual growth. Since then, for four years, the patient has been examined at regular intervals and the local condition remains unchanged. She is well and has grown fat, and the bowels open without difficulty per rectum. Colostomy has never been performed.

The interesting points are: (1) The age of the patient. (2) The success of radiation treatment in spite of the unpromising site, extent, and histological character of the growth. (3) The absence of either colostomy or rectal disability in spite of originally extensive malignant disease.

Parkinsonism following Peripheral Trauma

Apart from its appearance following encephalitis, Parkinsonism may appear as a sequel to manganese poisoning, senility, syphilis, arteriosclerosis, and various forms of trauma. Numerous records and review collections of cases of Parkinsonism following cranial trauma have recently been published. Among the best are those of Patrick and Levy (1922), Grimberg (1934), Kulkov (1932), and Bruetsch and DeArmond (1935).

Records of Parkinsonism following peripheral trauma are more scanty. Faure-Beaulieu (1932) gives a minute account of such a case in which the injury was to the arm. The details of clinical observation and commentary in this case are very convincing. Naville and de Morsier (1932) review with lengthy commentary forty-two published cases of Parkinsonism following peripheral trauma. They point out that such cases present the following characteristics: (1) In the interval between the injury and the full development of the Parkinsonian syndrome the injured limb remains weak, painful, and subject to sensory disturbances. (2) Tremors and hypertonus almost always appear in the injured limb. (3) The syndrome becomes manifest on the injured side. (4) Mental changes are absent.

In their commentary Naville and de Morsier (1932) quote Charcot as favouring the possibility of Parkinsonism from peripheral trauma, and they suggest that the peripheral injury brings about the cerebral illness by means of a subacute toxic ascending neuritis.

CASE HISTORY

In September, 1934, "B." had on his records no note of any illness of relevance or gravity. On that date his right hand was accidentally crushed, lacerated, and bruised. It became inflamed and lengthy local treatment was required. Although the wounds have long since healed the pain in the hand has persisted.

I first saw "B." in April, 1935, at the request of his union. I advised the union about the obvious results of lack of gripping power, etc., in the damaged hand, and made a private note, without any idea of what was to come, that the man appeared more timid and nervous than might have been expected. I also noted that he talked in a rapid monotone, but was misled when he assured me that this was due to loose teeth.

I next saw him in March, 1937. He told me that the pain in the right arm was still present. He said that the arm had begun to tremble about a year after the accident. He also stated that the right leg had also become tremulous about eighteen months after the accident. He now presented the typical Parkinsonian syndrome, with unilateral tremors, blank expression, forward gait and posture, and dry flat monotone.

As a result of my representations a satisfactory settlement in regard to compensation has been secured.

Reviews

DIAGNOSIS AND TREATMENT OF DIGESTIVE DISORDERS

The Diagnosis and Treatment of Diseases of the Stomach and Intestines. By William Fitch Cheney, B.L., M.D. (Pp. 378. 24s. net.) London: H. Milford, Oxford University Press. 1937.

The Diagnosis and Treatment of Diseases of the Liver and Biliary Tract. By John Phillips, M.B. Revised by Russell L. Haden, M.D. (Pp. 539; 58 figures. 32s. 6d. net.) London: H. Milford, Oxford University Press 1937.

In a volume of less than four hundred openly printed pages Professor W. F. Cheney has brought together the essentials of diseases of the stomach and intestines. After a short survey of the methods of examination, with a commendatory note on gastroscopy, the author proceeds to deal with the disease syndromes severally. It is noteworthy that he regards the state of chronic gastritis as established beyond question by modern *x*-ray and gastroscopic technique, a position which is not yet acknowledged generally by workers in the United States, though accepted here and in Europe for many years. After describing the general course of cases of gastric ulcer and its treatment, the author gives a separate and useful chapter on its complications, haemorrhage, perforation, pyloric obstruction, and hour-glass stomach. The chapter on cancer of the stomach is full and sound. In discussing the question of cancer originating on an ulcer base, Professor Cheney, while pointing out that the clinical history is often suggestive, finds that often with complete *x*-ray and chemical examination a certain diagnosis cannot be made. In these circumstances, he says, the only rational procedure in the dilemma is, if doubt exists, to treat the patient for ulcer and then judge by clinical progress and by repetition of the *x*-ray examination. But ulcers even already malignant may improve temporarily under treatment by diet and medication, and valuable time may be lost before proceeding to surgical measures. The author divides disturbances of the functions of the stomach into three groups: those due to organic disease of the stomach itself, those due to organic disease elsewhere in the body —for instance, in appendix and gall-bladder—and those due to faulty innervation without organic disease discoverable anywhere. It is noticeable that in the last generation this last group, the gastric neuroses, has dwindled into an insignificant section of most modern textbooks. The author is thoroughly up to date in this and in his recommendations for treatment. He reserves judgement about the efficacy of mucin treatment for gastric ulcer, and is unimpressed by the claims made for injections of histidine, which has been extensively advertised to the medical profession under the trade name of larostidin. Each diseased state is illustrated by type case-histories from the author's practice and the records of Stanford Medical School, and the book as a whole bears the imprint of his individual thought and opinion. The section on the diseases of the intestines follows similar lines. The methods of examination are discussed, then inflammation of the intestines and chronic ulcerative colitis under the headings amoebic, bacillary, tuberculous and non-specific. This last-named group appears to be less common than in this country. So, too, the modern author would combine the two chapters on ulcers of stomach and of duodenum into one discussion of peptic ulcer, since clinically they resemble each

other so closely that it is hard to distinguish one from the other by history and effects upon digestive functions. Professor Cheney makes the anatomical but arbitrary separation of the two by the pylorus, and this involves some repetition and redundancy. It affords an opportunity, however, of bringing in and describing diverticulum of the duodenum. A new form of inflammation of the small intestine was differentiated by Crohn in 1932, and is given a clearly written notice. This excellent volume may be recommended as sound and up to date.

Another volume of the same series is devoted to diseases of the liver and biliary tract. The author, Dr. John Phillips, after completing the manuscript, lost his life as a result of the disastrous fire in the Cleveland Clinic in 1929, and the book has been revised and passed through the press by Dr. Russell L. Haden. It contains a good account of the clinical aspects of the subject, preceded by short chapters on the anatomy and physiology of the liver and special methods of testing liver function. About 15 to 20 per cent. of cases of jaundice are non-obstructive, and the author follows modern teaching in regarding it as established that in catarrhal jaundice there is an acute inflammatory or degenerative hepatitis. He treats the various toxic forms of jaundice, from drugs and in Weil's disease, under the heading of jaundice, reserving an independent chapter for the cirrhoses. It is perhaps simpler pathologically to treat the whole series as a range of interactions of toxin and liver cells, but it may be more useful clinically to deal with the syndromes separately. Practitioners will obtain from the book all that it is necessary to know and each chapter is followed by a short bibliography. The illustrations are noteworthy, many in colour.

AN ACCOUNT OF BACTERIA

Fundamentals of Bacteriology. By Martin Frobisher, jun., B.S., D.Sc. (Pp. 474; 230 figures. 14s. net.) Philadelphia and London: W. B. Saunders Co. 1937.

Bacteriology has developed as an applied science. The relationship of bacteria to disease has in the past been the main preoccupation of bacteriologists, though the part played by these micro-organisms in agriculture and industry has also received attention. The result of this has been that few have had either the opportunity or the incentive to study bacteria for themselves as a purely academic pursuit. To-day, to some extent at any rate, there is a reaction against this one-sided approach to the subject, and the number of those who are interested in the science of bacteriology, quite apart from its important applications, is increasing. As evidence of this, textbooks are appearing in which bacteriology is treated in a broad and unspecialized manner, an example in point being the recently published *Fundamentals of Bacteriology*, by Dr. Martin Frobisher, jun., of the Johns Hopkins University. In this book of between 400 and 500 pages the author has attempted to give us a picture of bacteria as minute unicellular plants with many interesting and important activities—medical, industrial, agricultural—and so provide the student with that broad base on which the more specialized knowledge of one of the applied branches of bacteriology can, if necessary, be built. It is interesting to note that despite the author's avowed object there is a chapter devoted to pathogenic protozoa. Although it is usual to include protozoa in textbooks of bacteriology written for medical students, a practice which though regrettable is understandable, there can be no excuse for doing this in such a book as Dr. Frobisher has written, and it is to be hoped that in future editions he will leave this chapter out.

Generally speaking it can be said that the author has achieved his object. In the small compass of this book he has given us a readable, interesting, and accurate account of bacteria. It is divided into three sections. The first of these is devoted to general principles, the general properties of bacteria, the technique of their study, their morphology, physiology, and their identification. Section II is mainly systematic, opening with a chapter on classification, followed by accounts of the different genera. This section contains also interesting accounts of the bacterial flora of the soil and their rôle in soil fertility, and a chapter devoted to the industrial aspects of bacteriology. The third and longest section is concerned with the part played by bacteria in disease, and this is extended to include the rickettsia and the viruses. In the present state of our knowledge of the nature of these last two groups of disease agents it is perhaps permissible to include them in a book of this nature, and both these chapters are quite good, though it is rather difficult to follow the author's train of thought when he attempts to draw a parallel between the activities of the viruses of yellow fever and psittacosis.

The book closes with a chapter outlining the birth of the science of bacteriology. The usual practice is to introduce the subject by a historical survey, and that certainly seems the more logical procedure.

ANTIMONY IN MEDICINE

Ergebnisse und Fortschritte der Antimontherapie. By Professor Hans Schmidt and Dr. F. M. Peter. (Pp. 218; 8 figures. RM. 15.50; geb., RM. 17.) Leipzig: G. Thieme. 1937.

This book on the results and progress of antimony therapy contains a full review of an important subject. No other drug used in medicine has had such a chequered career as antimony. Introduced into medical practice by Paracelsus, it had, like its sponsor, a stormy and turbulent career, for its employment was bitterly assailed by the adherents to Galen, and the authorities of the University of Paris in 1560 forbade their graduates to use it, a veto which was maintained for 100 years. During the next two centuries antimony became the sheet anchor of the heroic school of therapy, but with the decline of this school the drug fell into disrepute, and by the opening of the present century its therapeutic use had almost ceased. It made, however, a remarkable recovery of a wholly unexpected nature when, in 1907, antimony tartrate was discovered to be a potent trypanocide. The importance of this was at first obscured by the development of the organic arsenicals, but later intensive research produced a series of organic antimonials, and to-day these rival, if they do not surpass, the organic arsenicals in respect of therapeutic importance. The most important uses of these organic antimonials are in the treatment of bilharzia, trypanosomiasis, and kala-azar.

Many hundreds of organic antimonials have been prepared; certain of these are of outstanding and well-established importance, such, for instance, as the trivalent compound fuadin or antimosan and the pentavalent compounds stibosan and neostibosan. The authors give a comprehensive survey of the literature relating to the use of antimony compounds in tropical diseases. It is interesting to note that the various compounds mentioned have highly selective and specific actions. The trivalent fuadin has proved superior to the pentavalent compounds in the treatment of bilharzia, but on the other hand neostibosan is more effective than fuadin in the treatment of kala-azar. Fuadin is an effective trypanocide as regards *T. brucei* and *T. congolense*, but is inactive against *T. equiperdum*.

The authors describe also three new arseno-antimonial compounds prepared in the Elberfeld laboratories of the I. G. Farbenindustrie which appear to be effective against a wide range of micro-organisms. One of these (Sdt.386B) has shown an activity in relation to bartonella infections which exceeds that of any known compound of arsenic or antimony.

A HANDBOOK OF OTO-RHINO-LARYNGOLOGY

Diseases of the Nose, Throat, and Ear. A Handbook for Students and Practitioners. By I. Simson Hall, M.B., Ch.B., F.R.C.P.Ed., F.R.C.S.Ed. (Pp. 423; 55 figures. 10s. 6d. net, post 6d.) Edinburgh: E. and S. Livingstone. 1937.

Dr. Simson Hall has written a book on diseases of the nose, throat, and ear of moderate size, intended for the use of the medical student and the general practitioner. For this limited purpose it is no doubt well suited, as some instruction will be found upon most points coming under these headings, and the author has brought his work up to date in essentials, including endoscopy. Owing to the size of the book the information given is in many important places superficial in character. Greater care in writing and the choice of illustrations would have provided space for additional detail, but so far as they go the descriptions are accurate. It is necessary, however, to comment on the statement that the ideal anaesthetic for oesophagoscopy is intratracheal insufflation of ether. When the inevitable explosion occurs this book may be quoted in defence of this practice, and the author would then find himself in a situation of no slight embarrassment.

Dr. Simson Hall has no doubt fully realized that he is competing with a number of other manuals designed on a similar scale, but he has evidently taken much trouble in preparing the book so as to present the subject in a practical way which will appeal to a large class of readers. It is not difficult to find omissions, but they are not of major importance.

SKIN TEMPERATURE IN HEALTH AND DISEASE

Hauttemperaturen. By Johannes Ipsen. (Pp. 375. 18 Cr.) Copenhagen: Levin and Munksgaard. Leipzig: G. Thieme. 1936.

It is only in quite recent years that the variations of skin temperature in health and disease have been seriously studied. In this work Dr. Johannes Ipsen of the State Hospital at Sonderborg in Denmark has been a pioneer in defining the various abnormalities of skin temperature met with in surgical cases. He has used for his measurements mercurial thermometers, and especially the thermo-electric apparatus of Hartmann and Braun. In the present book, which is embellished with many charts and diagrams, he now describes in full detail this rather unfamiliar field of knowledge. He passes briefly over the normal variations that are connected with the conservation of body heat and those that depend on the reactions to external heat and cold. Incidentally he makes very clear the wide differences in normal skin temperature in different parts of the body, and the great importance clinically of comparing the readings taken from corresponding parts on either side.

It is well known that the skin temperature at any point depends on the activity of the cutaneous circulation and that the flushed and heated skin in fever favours the loss of body heat, and that, on the other hand, when temperatures are subnormal the bloodless and pallid skin is favourable to the conservation of heat. But the parts played by the arterioles and capillaries are perhaps less realized. By the aid of an ingenious diagram of skin heat and colour Ipsen shows that increased warmth of the skin indicates dilatation of the arterioles, while the colour ranges from red to white according to the calibre of the capillaries. In injuries, operations (even abdominal), arteritis, aneurysm, phlebitis, etc., he attaches much importance to lowered temperature in the leg or foot, which may even indicate serious circulatory disturbance in advance of other signs. A few minutes after an embolism the foot temperature may fall as much as 9° C. Post-traumatic arterial spasm may depress the temperature 10° or 12°, the injured part (and this is important) losing its normal reaction to cold. Another interesting diagram shows the range of difference between superficial and deep temperatures in Graves's disease and in fever as compared with the normal.

Sufficient has been said to indicate the far-reaching value of Dr. Ipsen's work. The importance of skin temperature in diagnosis alone is too often overlooked. We can remember acute pains thought to be rheumatic and proved to be due to commencing phlebitis by a patch of raised temperature in the leg; and, again, cold areas on the upper arms or thorax, which were signs of more deep-seated circulatory disturbance. Although this book deals mainly with surgical conditions, it should be of wider interest at the present time, when clinicians are realizing the importance of local and general chill, both from the diagnostic and the therapeutic standpoints. Where these areas of cold are present it is often possible not only to restore the local circulation but to relieve more deep-seated disorders.

Notes on Books

The Condition of Britain (Gollancz, 7s. 6d.) is a survey of modern life in this country by those indefatigable writers, G. D. H. and M. I. COLE, who systematically cover the whole field, reinforcing the text with a lavish use of tables, statistics, and diagrams. The book deals with distribution of income and property, housing, unemployment, standard of living, education, taxation, and social services, in addition to many other subjects. Of special interest to medical readers is the long chapter devoted to health and nutrition. Here the authors conclude, not without some justification, that the existing situation is grossly unsatisfactory in certain respects. They refer in particular to maternal mortality and to the undernourishment which prevails among a third of the population. As sanguine as they are industrious, Mr. and Mrs. Cole have constructive ideas for the remedy of these and the many other evils that beset us. "If we want social betterment we must create, both here at home and as far as in us lies in the world as a whole, the psychological conditions which will make betterment possible." This is a valuable and informative book, and the reader, whatever his political opinions, cannot but be impressed by the ability and sincerity of the authors.

In *Pediatric Dietetics* (H. Kimpton, 32s.) Dr. N. THOMAS SAXL sets out to assemble and correlate available data on the subject of the dietetic treatment of the sick child in one volume. The result is a large accumulation of facts, often contributed by experts, which would be better appreciated if there had been more rigid pruning. Illustrations of sick children seem curiously out of place, and the brief descriptions of certain disease processes are quite inadequate. These drawbacks are to be regretted, for as a standard work of reference this volume contains much that is valuable, particularly the sections giving composition of food in regard to minerals and other essential constituents. Indeed, the appendix containing such tables and many recipes is the best part of the book.

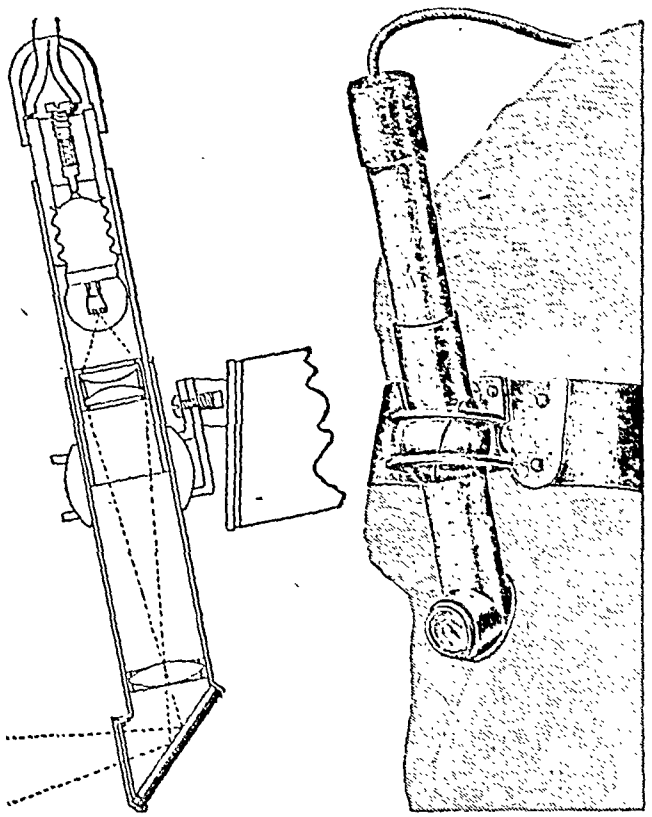
Dr. H. B. SHAFER writes an account of *The American Medical Profession 1783–1850*, which appears as No. 417 of Studies in History, Economics, and Public Law from the Faculty of Political Science of the Columbia University (London, P. S. King and Son, 14s. 7d.). Dr. Shafer deals first with American medicine at the close of the eighteenth century, when such influence as it had came from the medical teaching at Edinburgh with a small trickle from the Hunterian school in London. He then tells of medical education in the United States, and deals with the special problems resulting from deficient preliminary teaching of the students, medical centres separated from each other by great distances, and the want of central control. He mentions incidentally that in some schools candidates paid the professor an examination fee which was kept if he passed but returned if he failed. There is an interesting chapter on medical ethics and fees, from which it appears that the dollar was practically equivalent to the guinea charged in these islands. The United States has always been recognized as the home of journalism, and Dr. Shafer states that between 1795 and 1850 no fewer than 117 medical periodicals were published. The book is valuable but is not exhaustive; there is still room for a companion volume on the private medical schools, because Dr. Shafer deals principally with what in England would be called the faculties of medicine and surgery. His accounts of cupping, of the practice of medicine, and of surgical operations stand in need of revision by a skilled hand, for the author is a doctor of philosophy, not of medicine.

Dr. LOUIS CHAPELON'S *Le Rôle de la Lumière dans l'Accommodation* (Paris, Vigot Frères, 25 fr.) is a teleogical exposition on the significance of light as a factor influencing the mechanics of vision. He holds that quite apart from its action in exciting visual sensation, light is responsible for the process of accommodation, adapted for all distances up to infinity. From a review of comparative anatomy, embryology, and physiological optics he argues that in the course of evolution the intrinsic muscle fibres of the eye have become sensitive to light and respond by secretion of aqueous, and so directly affect the shape of the lens. He finds the plan admirable as a balance between the intrinsic and extrinsic forces operating on the muscle system of the body, allowing the maximum adaptation of the individual to the outer world.

The annual report for 1935–6 of the Swiss Research Institute for Tuberculosis and Alpine Climatic Conditions describes the continued progress of several researches. At the physico-meteorological observatory the reactions of the human body to varied weather conditions are being investigated. Researches in the pathologico-anatomical and bacteriological section include a study of the chemical constitution of the tubercle bacillus.

Preparations and Appliances

AN IMPROVED HEADLIGHT



Mr. G. W. MOREY, M.B., D.L.O., writes from Shrewsbury:

There are many headlamps on the market, but none are really satisfactory. For the past four years I have been attempting to design a better lamp than those usually obtainable, and though the design I now publish is, I hope, a marked improvement on former headlamps, it is realized that it, too, still leaves a good deal to be desired. Primarily this lamp has been designed to overcome the disadvantage of a tube projection between the eyes, which encroaches on binocular vision.

For any headlamp to be really satisfactory the following conditions should be fulfilled: (1) the light itself should be of high intensity, (2) there should be a clear focused circle of homogeneous light, (3) the diameter of the light circle should be controllable by some system of focusing, (4) the light axis should be as close to the visual axes as possible and parallel with them, (5) no part of the instrument should protrude into the line of vision, (6) it should be light in weight.

The headlamp which is depicted here fulfils these conditions. From a dry battery worn on a belt, current is supplied to a 4-volt or an 8-volt bulb. This bulb is of special design, having a closely wound spiral filament, placed close to the glass. By overloading up to about 30 per cent. these bulbs will give a very intense light without fusing, though after some twenty hours' use they may gradually turn black and require replacing.

The optical system through which the light passes has been very carefully worked out to give the maximum intensity. A condenser is fixed in a movable tube to allow focusing, while distal to the projection lens is a small mirror, set at 45° in order to turn the light beam through a right angle. This mirror is enclosed behind a plane-glass window so that it and also the projection lens do not get soiled.

The headband is cut on a curve and so fits comfortably on the head. The lamp is held vertically in a gimbal ring and can be moved in any direction. The mirror fits snugly against the bridge of the nose and is almost invisible, and in this position allows the light beam to coincide with the visual axes as nearly as is possible. The whole instrument is so light in weight that it can be worn for many hours without discomfort.

I am indebted to Messrs. Rayner and Co., 100, New Bond Street, London, W.1, who have helped me with my experiments and who have made this instrument.

NEW STETHOSCOPES

The Capac Company Ltd. (6, Old Jewry, E.C.2) have devised two new patterns of stethoscope representing the outcome of prolonged research in acoustics as applied to instruments. The chest pieces are of solid construction, supplied either nickel-plated or in aluminium. For each chest-piece there are interchangeable chest-ends so that concave or convex forms may be used. The model with dome and secondary annular diaphragm, when fitted with the convex end, renders heart and lung sounds very clearly. The head-frames are fitted with comfortable rubber plugs for the ears, while in one model a spiral spring between the arms maintains suitable compression. Detachable plug fittings unite the head-frame with the rubber tubes, allowing easy detachment if desired. These instruments are found in use to be both efficient and comfortable; the latter is a factor too frequently overlooked by the makers of stethoscopes.

GASTRIC DISORDER AMONG BUSMEN

A STATISTICAL INQUIRY

A report by Dr. A. Bradford Hill on "An investigation into the sickness experience of London transport workers, with special reference to digestive disturbances," was issued on July 7 by the Medical Research Council and the Industrial Health Research Board.[1] The Industrial Health Research Board has investigated health problems of importance to industry by the use of sickness statistics on three previous occasions. In 1927 an attempt was made, by utilizing the incidence of sickness recorded under the National Health Insurance Acts, to discover whether artificial humidity introduced into cotton-weaving sheds had any measurable effect on the health of operatives. Sickness statistics were also applied in investigations into the death rates of printers from tuberculosis and into the liability to respiratory affections of operatives working in the preliminary cleaning processes of cotton-spinning mills. On each occasion the Board has set up a special committee composed of equal numbers of employers and employed in the industry concerned; members representing the Medical Research Council's Statistical Committee; and members representing the Industrial Health Research Board. "It has been the duty of the scientific members to see that such inquiry has been framed and carried out strictly in accordance with scientific requirements."

In 1934 this procedure was applied to the investigation of the alleged excess of gastric sickness among omnibus workers, and a committee was appointed consisting of three members from the London Passenger Transport Board, three from the Trade Union of Transport and General Workers, and three independent scientific members. The committee unanimously decided that an answer must be sought to this question: "Do omnibus workers suffer from digestive complaints more frequently or more severely (or both) than other groups of workers of similar economic and social position?" The problem of causation could not be tackled until the question of incidence had been settled. To begin with, the inquiry had therefore to be statistical.

As Dr. Bradford Hill points out in his introduction, a recorded sickness rate is the end-result of many factors, the separate influences of which are not measurable. It was therefore important to choose, for the purpose of the investigation, a comparative group of workers for whom such extraneous influences as economic position, type and severity of occupation, degree of unemployment, sickness benefits, etc., were equivalent to those to which omnibus workers are subjected. Tramway workers were unanimously chosen for the comparative group, and the investigation was limited to London. Although a number of ill-defined complaints may be included under the term "gastric," there appeared to be no grounds for believing "that what was termed 'gastric' in busmen covered a wider number of conditions than did the same term as applied to tramway men." In the preface to Dr. Bradford Hill's able report it is stated: "It may now seem fortunate that the Board were alert to the problem, and were able to make a scientific and detached investigation before the question at issue became a matter of public controversy."

We reprint below Dr. Bradford Hill's conclusions, references to tables being omitted.

Summary and Conclusions

1. An examination has been made of the sickness records of omnibus and tramway workers in the employment of the London Passenger Transport Board, with the object of seeing whether the omnibus workers have an abnormal sickness experience from diseases attributed to gastric causes. The special committee supervising the inquiry agreed that the tramway workers should be taken as a standard of comparison, it being a belief of the men's Trade Union representatives that these workers are not affected by gastric illness to the same extent as the omnibus workers.

2. The sickness data used were extracted from the records of the London Passenger Transport Board, and related to *all periods of illness of fifteen days' duration or longer, the numerically large mass of shorter and less serious periods being ignored.* The diagnosis of the cause of sickness that had to be used was, usually, that given by the panel practitioner on the worker's first certificate of incapacity. It is certain that numerous errors will arise from this, but a test specially carried out showed approximately the same degree of error with regard to gastric sickness in all the occupational groups (for sickness of at least three weeks' duration).

3. The data were extracted for the years 1925–6 and 1933–5, and relate in all to more than a million and a quarter days of sickness. By means of the figures for the earlier years it was hoped that it might be possible to see whether, with changing conditions of the working environment, any changes in the sickness experience had occurred. It was found, unfortunately, that in 1925–6 the diagnosis of the cause of sickness was so frequently missing from the omnibus workers' records that these data were too unreliable to be put to any further use.

4. The analysis of the sickness experience of the occupational groups has, consequently, been confined to the data relating to the years 1933–5, in which years 871,258 days of sickness (of durations fifteen days or more) were recorded. Of this total 17,974 days lacked a diagnosis of the cause of sickness and were excluded. The final analysis therefore relates to 273,150 days of sickness recorded for omnibus drivers, 310,180 days for omnibus conductors, 138,050 days for tramway drivers, and 131,904 days for tramway conductors.

5. It is known that the age distributions of the omnibus and tramway workers differ considerably, more of the latter workers being at the higher ages of working life than of the former. It has therefore been necessary to compare the occupational groups age by age, and in reaching a comparative figure for all ages to allow for the differences in the age distributions. The allowance has been made by calculating for the omnibus drivers the figures that they would have shown in each of four age groups, and, by summation, at all ages, if they had the same sickness experience in those age groups as the tramway drivers. The omnibus conductors have been compared in the same way with the tramway conductors.

6. By these means it is found that the omnibus drivers at all ages had in 1933–5 a relative excess of gastric sickness (that is, in proportion to sickness from all causes) of 12–14 per cent. over the figure shown by the tramway drivers. In the same way it is found that the omnibus conductors at all ages had a relative excess of gastric sickness of 15–18 per cent. over the figure shown by the tramway conductors.

7. Expressed in a slightly different way it is found that, roughly, one day in six and a half of the total days of sickness (of over two weeks' duration) recorded by the two groups of omnibus workers was attributed to gastric causes, whereas if they had had the same experience as the comparable tramway groups the ratio would have been one day in seven and a half.

8. This relative excess varies very considerably with age. There is no clear evidence that the omnibus drivers suffered relatively unfavourable rates from gastric causes either at ages 20–29 years or at 50 years and upwards. The relative excess of sickness from these causes (*in proportion to all causes*) was confined to the ages 30–49, at which it amounted to some 20 per cent. in days of sickness experienced and some 13 per cent. in number of periods recorded. But at these ages their total sickness experience—that is, from all causes—was not unfavourable in comparison with that of the tramway drivers.

The relative excess of gastric illness (in proportion to all causes) amongst the omnibus conductors was mainly derived from ages 20–39, at which it amounted to 34–35 per cent. both for days of sickness experienced and number of periods recorded. But at these ages their total sickness experience—that is, from all causes—was not unfavourable in comparison with that of the tramway conductors. Since the excess of gastric sickness at all ages was 15–18 per cent. for conductors, it follows that this higher figure at ages 20–39 must be balanced by lower figures at other ages. In fact, though at older ages the total sickness experience—that is, from all causes—of the omnibus conductors was in excess of that recorded for the tramway conductors, there was no evidence at these ages of a relatively greater liability of the former to diseases of the gastric system (that is, in proportion to sickness from all causes).

9. The age groups in which the relative excesses of gastric illness amongst the omnibus workers are found are numerically important. About three-quarters of the total number of omnibus drivers are of ages 30–50, and about two-thirds of the omnibus conductors are of ages 20–40.

10. In short, taking only sicknesses of over two weeks' duration and a wide group of diseases attributable to gastric causes (and the original data did not, it was held, justify any subdivision of this group), it was found that there was, in 1933–5, some excess of gastric illnesses recorded amongst the omnibus workers as compared with the tramway workers in those age groups to which the majority of the former belong, though at these ages the total sickness experience, from all causes, of the omnibus workers was rather more favourable than that of the tramway workers.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JULY 10 1937

SURGICAL TREATMENT OF ESSENTIAL HYPERTENSION

To those interested in the recent development of surgery applied to the sympathetic and vascular systems it must long have been evident that the problem of essential hypertension would soon focus the attention of some of the more hardy pioneers in this field, for, as in all other obscure affections of the vessels, the belief has been widely held that essential hypertension is primarily a disorder of the sympathetic nervous system. And since the older physiologists taught the paramount importance of the splanchnic area in the control of the arterial pressure, operations for the relief of hypertension have chiefly been designed to interrupt the vasoconstrictor fibres to the abdominal viscera.

One of the simplest operations, developed by Peet and his collaborators at Ann Arbor, is supradiaphragmatic resection of the major and minor splanchnic nerve and of the tenth, eleventh, and twelfth thoracic ganglia on both sides. This has been performed on 100 patients suffering from essential hypertension with an operative mortality of 4 per cent.; in fifty-four cases followed from four to twenty-three months after operation the subsequent mortality was 15 per cent.[1] Freyberg and Peet[2] have described more fully the results in forty-eight cases followed for three months or longer. In nearly every case the blood pressure abruptly fell immediately after operation, but in most instances it rose later to a variable degree. Freyberg and Peet state that when the patients were last examined the blood pressure was within normal limits in 12.5 per cent., was significantly below the pre-operative level in 37.5 per cent., remained unchanged in 48 per cent., and had risen in 2 per cent. In those patients whose blood pressure was lowered the renal function, as estimated by the urea-clearance test, was unaltered or actually improved after operation. Relief of such symptoms as headache and dizziness is said to have been definite in about 68 per cent. of cases. Perhaps the most remarkable post-operative result was the resolution of albuminuric retinitis in five cases of malignant hypertension[3]; in four of these the blood pressure was much reduced; in one it was unaltered. A second operation—bilateral section of the anterior spinal nerve roots from the sixth thoracic to the second lumbar inclusive—has been performed in the Rockefeller Hospital, New York.[4] Besides interrupting the vasoconstrictor nervous impulses to the abdominal viscera, this operation paralyses the abdominal somatic muscles, thus, it is hoped, promoting the pooling of blood in the veins of the belly. The operation is performed in two stages, the requisite length of dura mater being exposed at the first and the nerves divided at the second. Twenty patients with essential or malignant hypertension and systolic pressures over 200 mm. Hg were so treated: of these one died on the table in a one-stage operation; one died of a streptococcal infection after the first stage; one developed a transverse myelitis after the dura had been exposed, with subsequent partial recovery of the paraplegia; and one refused the second operation. Sixteen patients on whom the operation was successfully performed were followed up for periods of one to twenty-nine months; of these three died later. In all cases the blood pressure fell slightly or considerably at the end of the operation and thereafter showed a variable tendency to rise; renal function was not impaired by the fall in the blood pressure. Subjective improvement was pronounced in fourteen patients.

These two operations seem to yield similar results. In a few cases there is a considerable and prolonged fall in blood pressure and marked symptomatic improvement; in others the operation seems to have had little permanent effect. Why there should be this discrepancy is not at all clear. Essential hypertension is merely a convenient label applied to a condition in which more than one aetiological factor may be involved, and the operative results may differ because at least two separate diseases are under consideration. The facts available do not, however, add substance to this speculation, for of two patients apparently similar in every respect one may respond well and the other not at all; some patients with the malignant type of hypertension obtain great relief and others none. Peet considers the only contraindications to operation are an age greater than 50 years, a rather high non-protein nitrogen content of the blood, cardiac failure, and possibly cardiac asthma. Page and Heuer's best results were in young women with an unstable temperament. Post-operative mortality figures make it doubtful whether splanchnic denervation materially alters the course of the disease. While judgement on this point is clearly premature, the doubt, together with the absence of any indication as to which patient is likely to respond favour-

ably, will probably prevent the wide practice of such operative measures until more information is available.

Whatever its direct contribution to the relief of human suffering, surgical intervention, when its results are carefully observed, rarely fails to add precision to our conceptions of the mechanism of disease. Here the failure of splanchnic denervation to lower the blood pressure permanently in at least half the cases proves that in them the raised blood pressure was not due to splanchnic vasoconstriction of nervous origin. This agrees with the experimental results of Prinzmetal and Wilson[5] and of Pickering,[6] who independently found that in essential and malignant hypertension the vessels of the forearm and hand remain abnormally constricted when deprived of vasoconstrictor nervous impulses. Page and Heuer regard the long-lasting fall of blood pressure in some patients as evidence for the vasomotor hypothesis; but it must be noted that the most conspicuous diminution of blood pressure in their series was in the patient who developed a transverse myelitis after exposure of the dura mater and whose anterior roots were never divided. Peet, on the other hand, thinks that the favourable results in some cases may be brought about by dilatation of the renal vessels, the idea being that in certain instances hypertension is due to renal ischaemia, a measure which Goldblatt and his co-workers[7] have shown to produce a marked and prolonged rise of blood pressure in the dog. As yet there is no evidence for this interesting speculation.

THE PREVENTION OF SILICOSIS

During the past few years the problem of silicosis has been very actively attacked in Canada by a group of investigators under the general direction of Sir Frederick Banting, and the scene of some of this work has been the McIntyre Porcupine Gold Mine, Ontario. Among the new facts that have emerged is the influence of noxious gases produced by blasting on the development of silicosis. Underground workers exposed to these gases in addition to dust appeared to be more liable to develop the disease than those in the crushing houses above ground, although the dust concentration in the latter was considerably greater than in the mine itself; the suspected adjuvant action of gases was then confirmed by animal experiment by W. D. Robson and others.[8] During the course of these and other experiments a technique for dusting animals has been developed which appears to be certain and expeditious in its results. The animals are placed in chambers containing a tumbling box in which loose quartz is rotated in a grinding medium, producing a high concentration of particles of suitably small size in the air of the chamber. Daily exposure of rabbits to quartz dust in this apparatus for the comparatively short period of six months or rather less apparently produces typical nodular silicosis with regularity, and hence furnishes a strictly imitative and reliable method of experiment for testing the effects of other dusts. The latest product of this series of researches, which is now reported by J. J. Denny, W. D. Robson, and D. A. Irwin,[1] breaks entirely new ground, and will be received with much interest. It is concerned with a possible method of reducing the solubility of silica in the tissues.

No one now disputes that siliceous materials cause fibrosis only after they have passed into solution in the body fluids, and studies of the solubility of various minerals which are now in progress may throw a good deal of light on their varying capacity for causing fibrosis. It is also well known that alkali increases the solubility of silica; cases of rapidly progressive silicosis have resulted from exposure to dust from a commercial product containing free alkali in addition to a siliceous powder. The possibility that some such action as this might be at work in accelerating the production of silicosis in miners does not appear to have been considered as fully as perhaps it should be, and the first part of the new work now reported in Canada consists of experiments which show that *in vitro* the solubility of quartz is increased by the addition of carbonates or hydroxides of magnesium and calcium. Such substances as these, if present in quartz-containing rock, may therefore exercise an important influence on its effect in the lung. There is, however, another and extremely interesting observation, which is that there are means of reducing the solubility of siliceous material. It is not altogether clear why the particular substance was chosen, and the authors themselves confess that they do not understand how it acts, but they find that the solution of quartz is almost entirely prevented *in vitro* by adding finely particulate aluminium. Moreover, if quartz dust is mixed with aluminium dust of the same order of particle size, the proportion of aluminium in the mixture being less than 1 per cent., this dust does not produce nodular fibrosis in the rabbit's lung. In spite of the presence of as much quartz in the lung as serves to cause proliferative fibrosis in controls receiving no aluminium, the only effect produced is a foreign body type of reaction.

It is evidently much too early to assess the significance of this observation fully, and it is also certainly far from clear whether its direct application in silicosis prevention is practicable. At the same time it does encourage the hope that on some such lines as these a method may be found either of so treating mine dust that its dangers will be much reduced or of treating exposed workers themselves in such a way that the consequences of their inhaling dangerous dusts will be minimized.

THE DEVELOPMENT OF CARDIAC ENLARGEMENT

The clinical methods of palpation and percussion are no longer to be relied upon to determine early changes in the size of the heart, for these methods are of limited use even in estimating slight enlargement of the left ventricle. Early alterations in the size of the heart are as a rule to be recognized only by radiography, the study of which has led to the separation of a variety of changes in the shape of the heart, characteristic of corresponding aetiological conditions. But the rate at which enlargement develops and the effects upon it of functional changes in the heart have remained relatively obscure, and for this reason the recent contribution[1] by J. H. Palmer is welcome. Serial teleradiograms and a few orthodiagrams of the heart in various conditions were taken over a period, in most cases, of several years: such serial records are difficult to collect in large numbers and therefore only a few cases are reported in each group. The change in the size of the heart with the advent of congestive failure is of fundamental importance, and Palmer finds that, after allowance is made for alteration in the level of the diaphragm—and, more rarely, for the effects of pericardial effusion—the increase is not great: what increase there is involves chiefly the auricles and superior vena cava. Nor is the disappearance of congestion accompanied by much diminution in size. Closely connected with the subject of congestive failure, and especially when associated with tachycardia either simple or due to one of the arrhythmias, is the problem of acute dilatation of the heart. By this is implied a rapid enlargement, even within a few hours, and, although it has long been accepted as a reality, satisfactory proof of its existence has not been forthcoming. Palmer's observations on congestive heart failure, tachycardia, the arrhythmias, and on the heart in acute nephritis—conditions in which there is a sudden increase in the load on the heart—negative the view that acute dilatation occurs. Most cardiac disease ends in failure, and when this happens the localized early enlargement is found to be supplemented by a more or less general increase in size. This is explained on the theory of back pressure—now once more in favour—as being due to the extension of engorgement from the chamber primarily affected to those behind it. Another factor thought by the author to help in the production of such generalized enlargement—or at least the appearance of a symmetrical increase—is the pericardium: when the limit of its extensibility in one direction is reached it will compel further increase in size in others. Although it is usual in cardiac disease to find gradual increase in size and gradual impairment of function, there is reason to believe that so long as the load remains constant and no pathological changes occur in the muscle the size remains fairly constant. In support of this certain cases of valvular disease and hypertension are mentioned. Progressive enlargement without obvious cause is perhaps often to be explained by coronary atheroma. Age may play an important part in determining both the extent of enlargement and the rate at which it takes place, and if, as Palmer's observations suggest, certain conditions such as hypertension have greater effects in both these respects in the young than the old, the greater capacity for growth of the tissues of the former serves as a possible explanation. The general validity of this conclusion, however, remains to be proved. Certainly there are exceptions—for example, the very slight enlargement seen in some young people with coarctation of the aorta and hypertension. The work embodied in this report attacks problems that have been long waiting solution, but which, because of the prolonged and laborious investigations necessary, have remained obscure. They should, and doubtless will, be continued and extended by others.

PHYSICAL EDUCATION IN GERMANY

A delegation consisting of senior officials of the Board of Education and the Scottish Education Department and a few other experienced observers lately visited Germany at the invitation of the German Government in order to study methods of physical education in that country. The report of this delegation (Educational Pamphlet No. 109) has now been published as a pamphlet of eighty pages by H.M. Stationery Office, price 1s. It deals with physical education in the schools, in the universities, in the various national associations, including the Hitler Youth, and in the organization known as Kraft durch Freude (Strength through Joy). It is mainly a descriptive document, but it also attempts to assess values and to compare German methods with those adopted in this country. Discussing the "Napoli" Schools (National Political Educational Establishments), of which there are fifteen, and which are a new feature of the German educational system, the report says that the aim of these schools is to train boys with a natural capacity for leadership for political, military, and other posts of special importance and responsibility. Many thousands of applications for admission are received every year, but the entrance standard is high and only exceptionally gifted boys have any chance of being accepted.

"The Hitler Youth organization is under an obligation to look out for and suggest the names of outstanding boys, and the head masters of the schools travel all over Germany to interview likely candidates and discuss their cases with people who know them well. Before entry a

searching physical as well as intellectual test is set, and the parents' consent must be obtained. . . . The programme of the 'Napoli' Schools has been drawn up in accordance with the Führer's own ideas. The first aim is the cultivation of healthy, hardy bodies, patient of toil and fatigue and heat and cold, and inured to stress and strain. Next comes the development of mental capacity, the formation of character, schooling in the exercise of will-power and determination, and training in responsibility and leadership. The last—and avowedly the least important—aim is to give the pupils proficiency in book knowledge and a grounding in academic subjects generally."

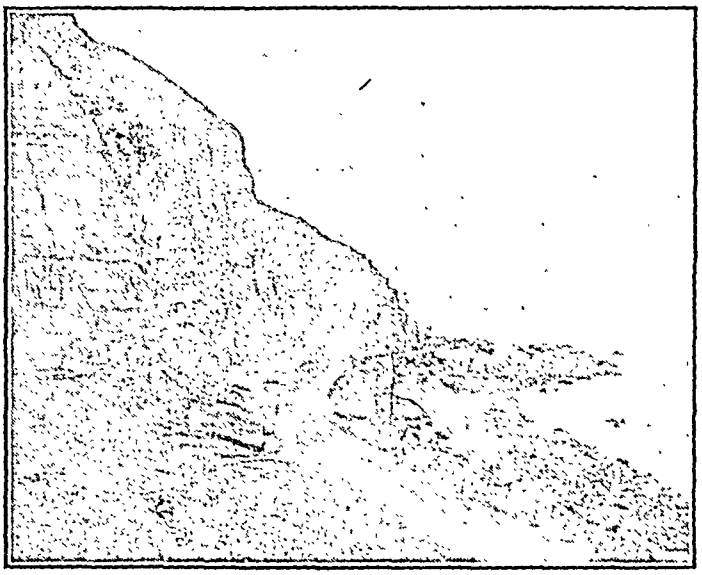
Physical training departments have been set up in all the universities, and by Ministerial decree every member of the German student body has to undergo a course of elementary training in gymnastics, athletics, and games during his or her first, second, and third semesters—that is, for eighteen months. Thus physical training is now recognized as an essential part of the general training of youth, and is given as important a place in the university course as that held by academic subjects. The report says that the Hitler-Jugend is the most efficiently organized youth movement in the world. There seems little doubt that the entire German youth is, as it were, to be conscripted into it and educated physically, morally, and politically through it, and any boy who has not passed through the movement will be debarred from a professional career in the service of the State.

"There is no doubt whatever that the Hitler-Jugend has caught the imagination of the young people, and no pains are spared to ensure that it shall make the strongest possible appeal to their emotions and adventurous instincts, and to invest it with an aura of high romance. . . . He is encouraged to read books and magazines of a type that would hardly be allowed to find a place in any school library in this country, and when he does read fiction it is often of such a highly sensational character as to make the most daring school stories and 'bloods' published in this country seem utterly feeble in comparison."

Commenting on Kraft durch Freude, the report says that it is for the foreigner the most agreeable and possibly the most instructive phenomenon of the Third Reich. The idea is

"to teach the German worker sensible ways of occupying his leisure; and Kraft durch Freude boldly faces the fact that the vast majority of people do not want to spend a great deal of their spare time sitting at home and reading books; they want to get out into the open, to exercise their bodies, to play games, and to do things rather than think things with their fellows. It is constantly dinning into the worker's ears that a man's life is not all toil and labour, and points out that he has the right to demand of the State that it shall cater for his leisure in this manhood as it catered for his education in his childhood. National Socialism, he is told, recognized the justice and reasonableness of this demand, and is taking effective steps to see that he can every day look forward to a complete change of occupation and a jolly one at that—after he has passed through the factory gates in the evening."

The report concludes with a chapter which raises the pertinent question: Is not the present German preoccupation with the subject of physical training likely to go too far, and is there not already a tendency in that country to seek to develop the body at the expense of the mind and to regard it as a mere machine to be kept constantly tuned up to the highest possible pitch of efficiency? One thing greatly impressed the delegation: a tenseness and ultra-seriousness of expression among the young people seen at work in the schools and in the Hitler-Jugend.



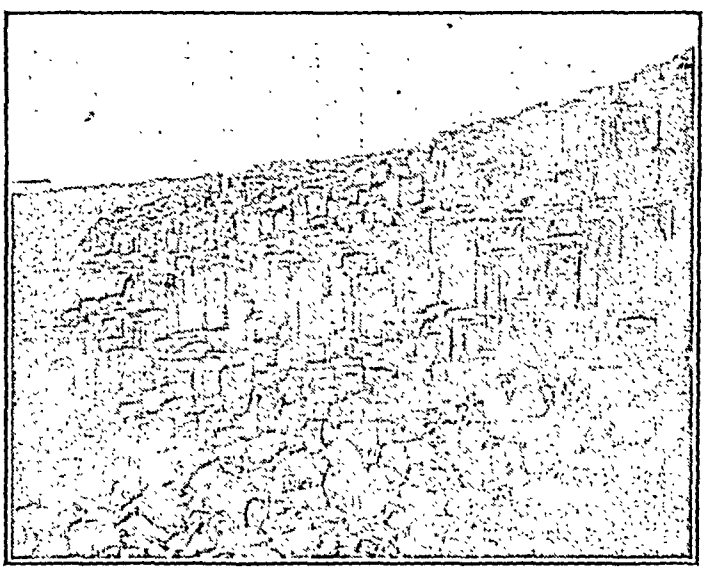
THE ENDOCRINES IN THEORY AND PRACTICE

As endocrinology has been extending its frontiers so widely during the past decade or more, and as the practising physician must find it increasingly difficult to distinguish between the rational and the extravagant claims made on behalf of endocrine products, we invited workers in this field to contribute the articles which appeared weekly in these columns between October 17, 1936, and May 15, 1937. We understand that in one university medical students were told by their teachers to "read the articles in the *B.M.J.*" if they wished to be informed of "the latest" in endocrinology, and that similar advice was given to postgraduates at another teaching centre. The appreciation of this series shown by so many must be as much a source of satisfaction to our contributors as it is to us. In response to requests that the series should be collected in book form this has now been done, and a volume entitled *The Endocrines in Theory and Practice* is published this week by Messrs. H. K. Lewis and Son, Ltd., at the price of 9s. In this volume each ductless gland is dealt with from both the scientific and the clinical aspect. The clinical chapters will, we believe, give the man in practice sound guidance on the uses and limitations of endocrine therapy, and enable him to assess more accurately the value of the attractive brochures that arrive with his morning's post. He will also gain instruction from the scientific chapers, for an understanding of the physiology of the endocrines cannot but make for more intelligent therapeutics.

A DIGEST OF TREATMENT

Another attempt to help those who feel overburdened with the gradually increasing literature on medical subjects has been made in the form of a monthly review of therapeutics, entitled *Digest of Treatment*, the first number of which appears this month. It is small enough to carry in the coat pocket, consists of eighty pages, and each issue will contain about forty to fifty extracts of articles on treatment which have appeared in the 200 medical journals surveyed by the editorial staff. This new venture is carried out under the general editorial supervision of Dr. George E. Rehberger, and is published by J. B. Lippincott Company, Washington Square, Philadelphia, the annual subscription being 25s., post free. In a circular issued by the publishers it is stated that "the editors are given absolute freedom in making their selections—no selections are made because they are favourable to advertisers. No advertising of any nature will be carried."

and Jura to the north and the coast of Argyllshire to the east are visible. It was on Rathlin that Robert Bruce took refuge after his defeat at Perth before finally avenging himself at Bannockburn; it was here also that the legend of Bruce and the spider originated. Of modern interest is the fact that Marconi's first experiments in wireless transmission were carried out between North Antrim and Rathlin. The road from Ballycastle leads westwards to the Giant's Causeway and Portrush. On the way are numerous beauty spots and scenes of interest. Kenbane Head, the village of Ballintoy, the rope suspension bridge at Carrick-a-rede, Whitepark and Murlough Bays form a succession of interests which anticipate the arrival at the Causeway.



Antrim Coast Road.

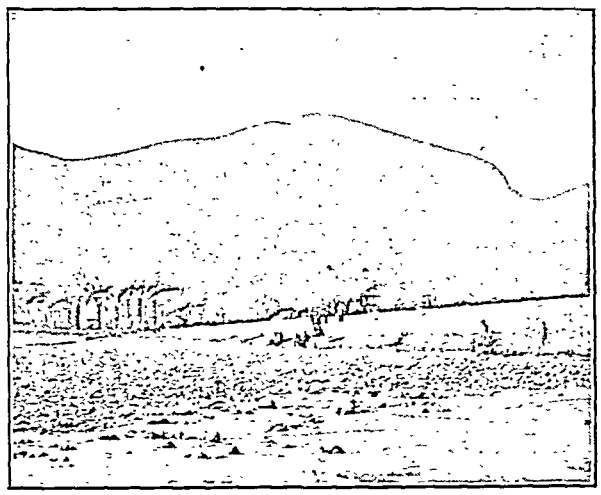
The Giant's Causeway

The Giant's Causeway is reputed to be one of the seven wonders of the world. There is nothing elsewhere like it, and herein lies its unexampled quality. The formation of octagonal columns, suggestive of the work of bees but on a grand scale, has been explained by geologists, but the native guide still maintains the theory of giant origin (Finn McCoul) with an eloquence that lacks nothing in conviction! The Causeway reaches out to sea with its "Giant's Well," its "Wishing Chair" among its novelties; along the cliffs are the "Chimney Stacks," the "Organ," the "Giant's Loom," and "Lord Antrim's Parlour," and at every point glorious views of sea and coast. The exploration of the caves of the head by boat is an experience, doubtless excelled by the Blue Grotto of Capri, but still unique on the coastline of these islands.

On leaving the Causeway the motorist passes through the village of Bushmills to meet the electric tramway which runs along the roadside to Portrush, the first electric tramway to be opened in the British Isles. Dunluce Castle stands on a promontory separated from the mainland by a deep chasm spanned by a narrow bridge. This picturesque ruin was obviously an extensive fortress with a communication via a cavern with the sea by which provisioning was carried out during siege. The origin of the castle is uncertain, but it is mentioned in fifteenth century history as having been occupied by McQuillans, MacDonells, and various Elizabethan commanders. Rounding the headland one sees Portrush in the near distance with the Donegal Highlands in the background. Between the road and the sea are the undulating hills where are laid the links of the Royal Portrush Golf Club, one of the three finest golf courses in Ireland and the equal of the most famous in England and Scotland.

Giants Causeway.

Portrush is a popular seaside resort. It is ideally provided with a three-mile strand of golden sand extending to the White Rocks, magnificent bathing facilities, and all the amenities for an ideal holiday with the sea breezes from the open Atlantic. Near by is Portstewart, quieter and more restful, but also provided with its golden strand, its golf course, and bathing. Across the River Bann (famous for its salmon fishing) is Castlerock, which lies on one of the routes to Derry.

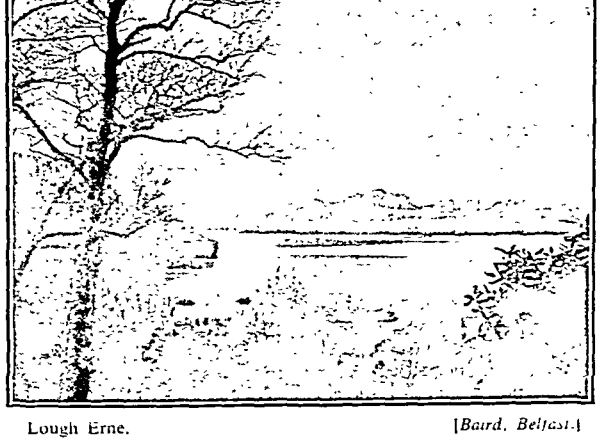


Londonderry

Derry is famous for its place in history and as the "Maiden City" of Ireland. It dates from the sixth century, when St. Columba founded an abbey there. History records the struggles of the natives against the Danes, the Anglo-Normans, and the English, as well as its status in the ecclesiastical realm. Derry was the scene of many battles through the ages. James I in his project of the plantation of Ulster included the creation of the county of Londonderry as well as the corporation of the city, conveying the whole county to "six and twenty discreet citizens of our City of London." These were called the "Society of the Governor and Assistants, London, of the new plantation in Ulster, within the realm of the Kingdom of Ireland." Thus ancient Derry became Londonderry, and the Irish Society was formed to promote religion, education, and industry in the newly constituted county. The Society has retained Londonderry and Coleraine as well as the fisheries of the Bann and the Foyle; the remainder of the properties was divided among the London Companies of Vintners, Grocers, Drapers, Goldsmiths, etc. To this day the Governor, who must be an alderman of the City of London, and members of the Society pay an annual visit to their properties.

The historic walls of Derry were completed in 1619 and the cathedral in 1633. In 1641 there was warfare again, in 1649 a siege of twenty weeks, and in 1688 the gates were closed by the apprentice boys against the soldiers of James II, and in April of that year began the famous siege of Derry, termed by Macaulay as the most memorable in the annals of the British Isles. For 105 days the beleaguered garrison and citizens suffered privation and hardship from which 7,000 persons died. Then came relief when the *Mountjoy*, leading the relieving ships in the Foyle, struck the boom of floating beams and drew alongside the quay, bringing succour to the survivors and setting to flight the investing army of James. The walls are in an excellent state of preservation so that the visitor

can readily walk around them and mentally recreate the scenes of 300 years ago. He can inspect "Roaring Meg," one of the guns used during the defence. He should not fail to visit the cathedral, rich in historical souvenirs of a city whose name at once "suggests religious animosities and protracted sieges."



Derry is a city of steep hills on the banks of the Foyle. It is the centre of the shirt-making industry and distributes its products far and wide; some thirty factories are engaged in this work. It is the natural distributing base for the neighbouring county of Donegal, and is an admirable centre for historical research, for interest, and for beauty. The Donegal Highlands are easily accessible, while to the south are the Sperrin Mountains and Lough Erne. The direct route to Belfast leads through the mountains, across Glenshane Pass, through Maghera, Toome, and Randalstown, to Antrim and Belfast.

Mourne Mountains from Newcastle: Slieve Donard in background.

Lough Neagh and Antrim

Less than a mile outside Antrim is Lough Neagh, the largest inland lake in the British Isles. Surrounded by wooded country it borders five counties with a hinterland of mountain in all directions. To the north is Slemish, on the slopes of which St. Patrick herded Milchu's pigs; not far from this spot he made his first convert to Christianity. Near to Antrim is one of the two perfect round towers in Ulster, although remains of others are found elsewhere. The origin of these peculiar structures was a subject of controversy among archaeologists, but all now admit that there is a close relationship with religious establishments of the early Church in Ireland. In the town of Antrim stands the cottage in which Alexander Irvine was born, author of one of the most poignant stories of Irish peasant life, *My Lady of the Chimney Corner*. Within a few miles of Antrim is Aldergrove, the R.A.F. aerodrome, and on the way to Belfast the route can include Ballinderry, where still stands Jeremy Taylor's church. It was here that the famous Bishop took refuge from the Puritans, and here he penned many of his works. Within seven miles of Belfast is Lisburn, rich in famous associations. Louis Crommelin, a Huguenot refugee, settled in Lisburn, and was appointed by William III to organize the linen industry in Ireland. His genius has borne fruit in the establishment of the staple industry of the North. Jeremy Taylor died in Lisburn, but the great figure is Nicholson of Delhi, who, with Henry Lawrence in Lucknow and John Lawrence in the Punjab, have engraved their names for ever in the history of the suppression of the Indian Mutiny.

Lough Erne. [*Baird, Belfast.*]

Down

Among the Irish counties Down is characterized by its undulating surface, its fertility, and its coast. The inlet of the sea (Strangford Lough) is notable for its multitude of islands. North Down, including the peninsula between the eastern shore of Strangford Lough and the Irish Sea, known as "the Ards," is famous for the ancient seats of learning at Holywood, Bangor, Movilla, and Greyabbey. On Strangford's opposite coast are a numbers of others at Ardmillan, Mahee and Nendrum, Raholp and Saul, the latter mentioned marking the landing-place of St. Patrick.

Along the southern shore of Belfast Lough the road leads through Holywood, past Clandeboye, to Bangor. Clandeboye is the seat of the Marquess of Dufferin and Ava. On the highest summit of the estate stands Helen's Tower, named after Helen, Lady Dufferin, granddaughter of Richard Brinsley Sheridan and great-grandmother of the present Marquess. Many literary notabilities have paid tribute to this gracious lady, Browning, Tennyson, Houghton, and Kipling among them, their contributions being inserted in the walls of the reception room of the tower. Perhaps the words of Tennyson are best known:

> "Helen's Tower, here I stand,
> Dominant over sea and land,
> Son's love built me and I hold
> Mother's love engraved in gold,
> Love is in and out of time;
> I am mortal stone and lime. . . ."

Bangor, a popular watering-place twelve miles from Belfast, was once the seat of a great monastic foundation, known throughout Europe as a centre of learning and piety from which went forth famous missionaries to various parts of the Continent. In Milan is preserved a priceless manuscript, the book of anthems used in Bangor Abbey in the seventh century. To-day Bangor is a populous borough, and is regarded by many as the villa town of Belfast. Its views include those of the Antrim coast on the north and the outline of the Wigtownshire coast to the east. Yachting is full of interest in July, when the annual regatta attracts the famous yachts from the Solent. It was from the Royal Ulster Yacht Club that the late Sir Thomas Lipton issued his challenges for the America's Cup with his famous *Shamrocks*. These graceful boats, along with their competitors, are as familiar here as on the Clyde.

From Bangor the coast road leads southward through Donaghadee, Ballywalter, and Cloughey to Portaferry, and thence northward along the east coast of Strangford

Lough to Newtownards, the seat of the lace embroidery industry. The monument on Scrabo Hill, erected as a memorial to the third Marquess of Londonderry, dominates the picture and can be seen from many parts of Ulster. Newtownards lies at the base of the Ards peninsula, and is notable for the beauty of the countryside and the distant views of the Mourne Mountains. Mountstewart, the residence of the Marquess of Londonderry, occupies an ideal situation. Its beautiful gardens, stocked with the rarest and choicest of blooms, are a feature not easily forgotten. The gardens at Greyabbey are overshadowed by the interest in the Cistercian abbey, founded in the twelfth century by John de Courcy, and occupied until it was finally abandoned in 1543.

The Kingdom of Mourne

As County Antrim is famous for its Giant's Causeway and glens, so is the county of Down proud of the splendour of the Mountains of Mourne, at the foot of which lies Newcastle. One route to this seaside town is by way of Killyleagh to Downpatrick, close to which St. Patrick founded two churches in his evangelizing mission. It is claimed that Downpatrick is his burial-place, and a huge stone marks the site of his reputed place of sepulture. The sandy low-lying coastline is in marked contrast with the ruggedness of Antrim, so that all the seaside towns and villages of Down are attractive for their sandy beaches and strands. Ballyhornan, Dundrum, and Tyrella lead to the climax of Newcastle nestling beneath the shade of Slieve Donard, the part of Mourne whose mountains "sweep down to the sea."

Newcastle owes its position in popular favour to its natural attractions. It is the home of the Royal County Down Golf Club, one of the most famous and best known courses in the world. Demesnes and gardens abound on the slopes of the mountains, and the horticulturist will find his time passing all too rapidly as he envies the possession of shrubs and alpines abounding in the luxuriance of their growth. From Newcastle the beauties of the Mourne Mountains can be explored by car or on foot. Slieve Donard appears to rise from the water's edge; Slieve Bignian with its crown of ragged crags lies to the south, with Bernagh and Commedagh and the other peaks in company. The Silent Valley has been impounded to provide an enormous reservoir which supplies Belfast with an abundance of excellent water.

From Newcastle the road continues round the coast through Annalong and Kilkeel to Rostrevor, sheltering under the southern aspect of the Mournes where they reach Carlingford Lough. The climate is particularly mild, so that exotic shrubs and plants grow as in the profusion of a Riviera climate. Woods of oak, ash, and pine abound on grassy mountain slopes. Carlingford Lough is an inlet between the mountains of Mourne on the north and those of Louth on the south. The coast road from Rostrevor provides many changing views of both until Newry, the "gap of the North," is reached. Newry is one of the most ancient towns in Ireland and the centre of a district teeming with historical memories. It lies on the main Dublin-Belfast road, leading through Banbridge, Dromore, Hillsborough, and Lisburn to Belfast.

Armagh

The history of Armagh dates to the pre-Christian era, and it is reputed to have been the seat of the warrior Queen Maha in 300 B.C. Much of the history of Ireland could be written around the cathedral city of Armagh, the ecclesiastical centre of Ireland since the days of St. Patrick. The Protestant Cathedral stands on the site where Patrick built his first cathedral in 445, and some maintain that a portion of the present building dates from the eighth century. Within the sacred edifice are famous sculptures as well as regimental colours, including a French colour (the only enemy colour ever captured within the British Isles) taken by the Armagh Light Infantry in 1798. Brian Boru, famous in the ancient history of warfare in Ireland, was buried close to the cathedral site, after a battle in which were defeated the Danes and Northmen who had ruled Armagh and maintained a fleet on Lough Neagh. The Roman Catholic Cathedral reared on a hill on the opposite side of the valley is notable among other features for the beauty of its ceiling mosaics and its peal of bells. The observatory, dating from 1790, contains the largest telescope in Ireland as well as a collection of unique clocks and instruments. The Primate's Palace, standing in its own grounds, possesses portraits of all Primates since Henry Usher (1595). "The Book of Armagh" includes a record of the life of St. Patrick written by himself and a copy of the New Testament written in 807.

From Armagh the road leads through Portadown and Lurgan to Lisburn and Belfast. Portadown and Lurgan are thriving industrial towns just five miles apart, set in the midst of the fruit-growing country which has gained for Armagh the title "The Garden of Ulster." In springtime the multitude of orchards in their blaze of blossoms would evoke the admiration of the most prosy, and would compare with the magnificence of the festival of cherry blossom in Japan. "Æ" (G. W. Russell), poet, painter, and journalist, was born near Portadown, and in the town Sir Robert Hart ("the most influential and most upright European the East has ever known") saw the light of day.

Tyrone and Fermanagh

To the south and west the road from Armagh leads to Dungannon and Enniskillen; or the east through Banbridge to the Mournes and Newcastle. Strabane, Dungannon, and Omagh are important towns in Tyrone, the first mentioned being the gateway to Donegal and its highlands. Dungannon is the educational centre, dating from the erection of the Royal School founded by James I. Omagh is the county town and administrative centre. The range of the Sperrin Mountains lies in Tyrone and can be easily explored from Omagh. It provides a magnificent panorama of bleakness and grandeur, of wildness and beauty, that is not always realized. Gortin Gap, Barne's Gap, the Glenelly River, and the village of Sperrin are well worth including in a circular tour from Omagh. The rivers are notable for their angling resources, so that the Mourne and the Blackwater among many others have their devotees of this art.

From Dungannon or Omagh the town of Enniskillen, the capital of Fermanagh, the stronghold of the chieftain Maguires, is on the route to the west. The town has its situation on an island in the river which connects Upper and Lower Lough Erne. It occupies a distinguished place in the annals of the British Army in that two regiments, the 6th Inniskilling Dragoons and the Royal Inniskilling Fusiliers, originated and developed out of the town. Enniskillen, however, has other claims upon our attention in view of its relation to Lough Erne. The lower lough provides a sheet of water studded by innumerable islands covered with trees and a luxuriant growth to the water's edge. This famous lakeland area of Ireland compares favourably with the better-known Killarney, and yields nothing in its appeal as a beautiful picture. An excellent motor road winds for some twenty-five miles along the southern shore to Belleek, noted for its potteries, and on across the border to Ballyshannon, Bundoran, and the Atlantic. The land border can be avoided by diverting at Boa Island and returning to Enniskillen along the opposite shore. A day spent in Tyrone and Fermanagh, in the Sperrin Mountains, on the shores of or afloat on Lough Erne, will provide scenes and experiences reminiscent of Killarney and the Scottish Highlands, or of English lakeland and Yorkshire moors. There is much of interest in and around Enniskillen, but all will wish to see the Round Tower on Devenish Island, the best preserved of

these ancient structures in Ireland. Standing some 80 feet high it retains the beauty of form and perfection as it did in the sixth century when it was constructed by St. Molaise.

There is much else to be seen in Ulster. This sketch, taking at random places of interest and character, serves but to indicate the variety which is available to every type of visitor. Good roads abound for the motorist; the angler will find his paradise in some well-known river or secluded stream; the golfer will test his skill on many courses of different qualities, but always midst beauty and harmony of scene. The archaeologist might spend a lifetime in studying the remains of an ancient civilization, and the historian will find that the history of the Empire has its thread in almost every town and village in the country. The inhabitants are reputed to be dour and undemonstrable, but this is an injustice as they are among the most hospitable of folk, although at times rugged in their character. The journey to Ulster is easily made by fast comfortable channel steamers. Every year there are increasing numbers who "discover" Ulster and return to make further acquaintance with its many attractions, not the least of which are the qualities of its kindly and thrifty peoples.

BRISTOL TUBERCULOSIS CONFERENCE

The twenty-third Conference of the National Association for Tuberculosis took place last week in Bristol by invitation of the City Corporation. The meetings in the University buildings were largely attended by tuberculosis officers and lay members of authorities throughout Great Britain. In the absence, through illness, of Sir Robert Philip, president of the Conference, appreciative messages were sent to him, and the chair was taken at the various sessions by Dr. R. A. YOUNG, Professor LYLE CUMMINS, and Dr. F. C. H. COUTTS.

Methods of Propaganda

Opening the first subject, "Propaganda and Publicity Methods," Dr. HARLEY WILLIAMS stressed the point that propaganda was one of the modern weapons in the fight against tuberculosis and sufficiently utilized. It was the science of good will, and should teach the profession the authorities, and the public the social meaning of the disease. At every turn we were handicapped by wrong attitudes, and these could be minimized by effective propaganda. He was afraid that doctors regarded it as somewhat unbecoming, and perhaps even unprofessional. This was unjustified if propaganda were properly understood. The programme must be regular and persistent, and should teach that disease was not inherited, that the worst victims were among the young, and that most of the cases of the disease were curable, given time and proper treatment.

Dr. VERONICA DAWKINS (East Anglian Sanatorium) described the measures in dealing with young women who had been patients in sanatoria. Health instructions throughout the country varied in amount, and were often omitted. Dr. Dawkins described the more advanced measures of popular treatment at present used in Germany, Italy, and among the negroes of the United States. Efforts in this country lagged considerably behind those of the Dictator nations. Most critics of propaganda were themselves non-constructive.

Mr. PAUL SCOTT RANKINE (Central Council for Health Education) detailed the new national campaign with which the Ministry of Health has entrusted his council. This is the first occasion in England when a Treasury grant has been given to aid popular health education. Its object next spring will be to popularize the use of the health services, and elaborate measures of advertising, newspaper publicity, and the use of films, leaflets, etc., are projected by the Central Council. Mr. Rankine described the many ways in which local organizations can cooperate in making these services fertile in their own areas.

Open-air Schools

The second subject, "Preventive Institutions (with Special Reference to Open-air Schools): (*a*) Environment," was opened by Dr. RALPH P. WILLIAMS (Board of Education), who described in a very lucid way the origin of open-air school methods, and showed lantern slides of the progressive improvements in the design of such buildings. It is evident that school architecture has been considerably influenced in the last thirty years by the open-air school as such. Open air stimulates metabolism, improves the appetite, increases resistance. The following children are chiefly selected for admission: (1) tuberculosis "contacts," (2) children convalescent after respiratory infections, etc., (3) children with defects of speech, eyesight, etc. There are at present in Great Britain only ninety-six day open-air schools and fifty-three residential open-air schools, but over three-quarters of the plans submitted to the Board of Education of ordinary school buildings are considerably influenced in design by the open-air principle.

Mr. GEORGE WIDDOWS (formerly architect to the Derbyshire County Council) described the evolution of open-air school design. Mr. NORMAN WHATLEY (head master of Clifton College) spoke on the conditions which should be provided for adolescent boys. He said that modern school buildings were a great improvement on the older ones, and diet to-day was regarded as a serious business. Sufficient sleep was of great importance, and was the chief advantage the public-school boy possessed over others less fortunate. He was afraid that perhaps conditions in public schools were tending to become too "soft." Physical instruction was popular just now, but probably the English would always prefer games to mere routine exercises. Mr. F. C. WILLIAMS (Bristol Corporation) described the development of specialized institutions under his committee, and the arrangements for staff, feeding, and transport.

Dr. N. T. K. JORDAN (Breconshire) described his experience in a residential institution for sixty boys, aged 5 to 14, in Mid-Wales. The cases were all ambulant, and included contacts with tuberculosis, sputum-negative cases of disease, and convalescents. Schools of this type were the answer to those who said that they were not paying enough regard to prevention in the campaign against tuberculosis. Dr. J. E. WILSON (Mansfield) described the remarkable open-air school at Berry Hill. He emphasized the different nature of the school curriculum as giving more attention to nature study and self-expression. Physical training received there twice as much attention as in ordinary schools. Dr. Wilson said he believed in special teaching of deep breathing to children, and argued that habits so formed are of permanent value. Open-air schools ought to be combined with nursery schools.

Nutrition and Tuberculosis

The second part of the subject dealing with nutrition in tuberculosis, from the preventive point of view, was opened by Professor J. A. NIXON (University of Bristol). Nutrition was not merely feeding; adequate rest, exercise, and emotional factors greatly influenced it. Dietetic measures by themselves would not prevent or cure tuberculosis. Nevertheless correct diet was an important factor in resistance. Professor Nixon emphasized the need for proper balance of the various ingredients, the avoidance of overstuffing and excessive doses of cod-liver oil.

Dr. P. A. GALPIN (West Ham) developed his theme of habit in diet. He found that many of his child convalescents

disliked green vegetables or fats, or were "faddy" in their habits of feeding. This was associated with catarrhal states. He himself followed the policy of controlling the child's diet in the light of physiological facts. Other speakers, notably Dr. MEIXNER (Illinois, U.S.A.), drew attention to those workers who found that children improved greatly when allowed, within limits, to select their own food. Other members of the Conference argued that social and economic conditions were the foundation of the problem. Between these two extremes opinion varied considerably.

The Tuberculosis Dispensary

The third subject, "Equipment and Activities of a Tuberculosis Dispensary," was opened by Dr. CAMPBELL FAILL (Bristol), who described the new central clinic about to be opened in Bristol, which has a population of nearly half a million. The object is to give personal attention to each patient, and adequate clinical and *x*-ray examinations. Dr. Faill said that the making of appointments facilitated the work. Reports in improved fashion were sent to the private doctors. There was complete co-operation and a common filing system with the maternity and child welfare department.

Dr. L. J. SHORT (Somerset) described the arrangements in a large and scattered rural area. There could be few clinic buildings and the scheme must depend largely upon the health visitor and a mobile tuberculosis officer. In some cases travelling expenses for patients were paid by the authority; in others the tuberculosis officer visited the patient at home. A summer camp for boy and girl "contacts" was proving successful in Somerset. Dr. MELVILLE HILEY (Glamorganshire) drew attention to the problems in a much depressed urban area. He emphasized the need for reassurance and the mental relief which accurate diagnosis must give. The general practitioner was still essential in the control of "contacts." In the Rhondda Valley 64 per cent. of the cases referred to the dispensary were found to have no tuberculosis.

Dr. MUNRO (Glenlomond) spoke of *x*-ray examinations, deploring the reliance placed upon a negative film as excluding tuberculosis. Radiology was an important weapon if wisely used, both in the "contact" cases and those who showed no symptoms of the disease, as well as in active patients.

The third day of the Conference was devoted to tours to Frenchay Park Children's Hospital and Ham Green Sanatorium, maintained by the Corporation of Bristol. The delegates also visited Winsley Sanatorium, near Bath—a voluntary institution.

At the annual meeting of the National Association, after the transaction of formal business, Dr. NOEL D. BARDSWELL gave an interesting account of his work on the Special Commission in Cyprus, of which a report appeared last week at page 30.

The following resolution was proposed by Dr. DIXON (Birmingham) and carried with acclamation:

> "That this Conference in the fiftieth year since the establishment of the Tuberculosis Dispensary by Sir Robert Philip, reaffirms its belief in the dispensary method of eradicating tuberculosis, and sends cordial greetings and congratulations to the Founder."

The first of a series of leaflets describing standard methods for the detection of toxic gases in industry has been issued by the Department of Scientific and Industrial Research. It is concerned with hydrogen sulphide and describes a relatively simple method of drawing a known volume of air through paper treated with lead acetate. The presence of hydrogen sulphide is indicated by a brownish staining of the test paper, and the degree of concentration of the gas can be gauged by comparison with a colour chart. The leaflet is obtainable from H.M. Stationery Office (price 3s. 6d. net).

BRITISH ORTHOPAEDIC ASSOCIATION

SPRING MEETING

The British Orthopaedic Association, under the presidency of Mr. W. R. BRISTOW, held its spring meeting in May in Copenhagen and Stockholm. The party consisted of some sixty members and their ladies.

Proceedings in Copenhagen

Three days were spent in Copenhagen, of which two were devoted to visiting the new Orthopaedic Hospital on the outskirts of the city. An attractive programme was arranged by Dr. Paul Guildal and his colleagues, and consisted of operative demonstrations and presentations of short papers.

Dr. GUILDAL gave an account of the functions of the Danish Orthopaedic Hospital, outlining the origin and progress of the treatment of the crippled child in Denmark. The whole service in Copenhagen was financed by the State, and the medical staff were all salaried officials. In a second paper he discussed the principles and results of the orthopaedic treatment of infantile paralysis. His practice and results corresponded closely with British views on this subject.

Dr. BENTZON advocated the use of drilling osteoclasis in preference to osteotomy, chiefly for the correction of outward curvature of the tibiae due to rickets. Through a small incision multiple drill holes were made in a transverse line at the apex of the deformity. The bone was then broken manually or with an osteoclast. Dr. Bentzon hoped that this simple operation would restore osteoclasis to favour, and suggested that experience would probably show that it had an even wider field of application. He next demonstrated the result of an operation for the treatment of paralysis of the gluteus medius. The insertion of the upper two-thirds of the gluteus maximus was brought upwards and forwards to occupy a true lateral position on the crest of the ilium. The patient whom he showed walked without a trace of limp, and could stand on the affected leg with perfect balance.

Dr. KIAER in the treatment of joint contractures had found infiltration with local anaesthesia of the capsule of the affected joint and active mobilization very helpful. Similar methods could be employed usefully in the treatment of recent sprains and of painful scars. He showed two patients who had been treated for sciatic scoliosis. He had found that immobilization of the lumbo-sacral spine in plaster-of-Paris jackets, applied with the patient suspended or bending forwards, gave the most satisfactory results.

Dr. STAERMOSE said that though *coalitio-calcaneo-naviculare* in many people represented no more than a symptomless anatomical anomaly, yet it was occasionally found in association with spasmodic flat-foot. Excision of the bridge between the two bones and the interposition of part of the muscle belly of the extensor brevis digitorum usually resulted in cure of the peroneal spasm. Dr. FOGED demonstrated the results of operations for torticollis. The most universally satisfactory procedure had been open division of both heads of the sterno-mastoid just above the clavicle, followed by a long period of daily stretching and re-education. Dr. CHIEVITZ gave an account of the geographical distribution of tuberculosis in the Danish population, and discussed the relationship between human and bovine types in surgical lesions.

In a brief symposium on osteo-arthritis of the hip Dr. MORVILLE dealt with the classification of this disease from the clinical and radiological standpoints, while Dr. BERNTSEN described his method of drilling ("forage") the femoral neck and head—the procedure described originally by Graber-Duvernay. It was interesting to hear that very considerable relief of pain had followed

this simple operation in over 60 per cent. of his series of patients suffering from osteo-arthritis of the hip.

Dr. THERKELSEN discussed in great detail the indications for and results of "shelf" operations performed in adult life for congenital subluxations of the hip. In contrast with the experience of British surgeons, Dr. Therkelsen had found the operation satisfactory in relieving pain and increasing the stability of the hip.

The visit ended with a tour of the hospital, which conforms with the modern standards of architectural simplicity, having many small wards containing at the most six beds. The British Orthopaedic Association dinner was held at the Restaurant Nimb, and among the guests were the Danish contingent and their ladies. Numerous social functions included tours in and around the city, a reception at the Yacht Club Pavilion by several of the Danish surgeons, and another at the Town Hall by the City Council of Copenhagen. All were keenly enjoyed by the visitors.

Proceedings in Stockholm

In this city two mornings were spent at the new Karolinska Institutets Orthopediska Klinik Vanföreanstalten, where Professor Waldenström and his colleagues and assistants presented a most stimulating programme.

Professor WALDENSTRÖM showed the results of arthroplasties on various joints, and concerning arthroplasties in general said:

"The treatment is, as we all know, difficult. But the difficulty lies not only in carrying out the operation skilfully, but as much in deciding which cases are suitable for operation. It should be undertaken only on the earnest request of the patient, and only after the surgeon has assured himself that the patient will really get more use from a mobile joint than from his present stiff one. We keep all these patients in hospital for some time before making a decision, not only for the purposes of physical examination but also, and still more important, to get an impression of their mentality and their reaction. The post-operative treatment is painful, and the patient must not only submit to passive movements, but he must also carry out energetic active ones many times each day in spite of pain."

Later he presented some of his views on certain hip conditions of which he has made a life-long study. These included coxa plana (pseudo-coxalgia) and coxa magna-valga-luxans. He attributed the latter to a mild local inflammatory process, possibly tuberculous in some patients, which resulted in overgrowth of the femoral head so that it was no longer contained completely within the acetabulum. The relationship between osteo-arthritis and the congenital and youthfully acquired deformations of the femoral head were discussed. Professor Waldenström also performed the operation which has been most successful in his hands for the treatment of recurrent dislocation of the shoulder—namely, the insertion of an autogenous bone graft into a niche along the anterior margin of the glenoid (Eden-Hybbinette operation).

Dr. FRIBERG read a paper on spondylolisthesis, a condition which was being recognized more frequently in Sweden. When it was causing symptoms he advocated fusion of the slipping vertebral body to the spinal segment immediately distal to it through an abdominal transperitoneal approach. He performed his own modification of this operation on a patient during the course of the meeting.

Dr. KNUTSSON gave a brief but detailed account of the radiological findings in sacralization of the fifth lumbar vertebra. He emphasized that symptoms could arise not only from arthritis in the joint between the sacralized transverse process and the sacrum, but also from arthritis in the smaller intervertebral joints of the lower lumbar segments. Dr. Knutsson demonstrated, too, radiographs of many other interesting bone and joint conditions. The very high standard of radiographic achievement in this clinic was commented on by all the visitors.

Dr. SILFVERSKIOLD described the condition known as chondromalacia patellae and its treatment. He regarded it as the commonest form of derangement of the knee, and believed that the cartilage of the patella was the first in the body to undergo degenerative changes. There were crepitations between the patella and femur on movement, associated with attacks of pain and swelling, and peripatellar tenderness. For mild lesions he advised conservative treatment, and for more advanced ones excision of the damaged cartilage in part or in whole, the raw area being covered with a free fascial graft. About seventy patients had been operated on in this way and the majority had perfect function.

Dr. NILSONNE gave an account and showed some of the results of the operative treatment of infantile or congenital coxa vara. He had performed a wedge osteotomy in the trochanteric region on no less than sixty patients suffering from this condition. His best results were in those patients on whom the osteotomy had been done between the ages of 6 and 8. In these cases successive radiographs showed that the femoral neck had reconstructed itself over a number of years until eventually the hip could not be distinguished from the normal either by clinical or *x*-ray examination. This address and demonstration were among the most impressive seen on the Scandinavian visit and excited much appreciative comment.

Other short papers were read: on the rehabilitation of the cripple, by Miss HOJER; on the syndrome of the scalenus anticus and cervical rib, by Dr. WIBERG; on congenital ulnar deviation of the fingers, by Dr. LUNDBLOM; and on the results of the shelf operation for congenital subluxation of the hip in adults, by Dr. SEVERIN.

A COMMEMORATIVE EVENING

The *Medical Officer* was founded in 1908 as a weekly journal for medical men in the Government and municipal services under the editorship of Captain G. S. Elliston, *M.C.*, now Member of Parliament for Blackburn. It has throughout had the support and collaboration of public health officers. Its editor is a son of the late Dr. W. A. Elliston of Ipswich, President of the British Medical Association in 1900, and a brother of Mr. Guy Elliston, who was Financial Secretary and Business Manager of the Association from 1902 until his death in 1918. The *Medical Officer* reached its 1,500th issue a few weeks ago, and in commemoration of this landmark Captain Elliston gave a dinner party at the House of Commons on July 1 to meet the President and Council of the Society of Medical Officers of Health.

The Registration Act, 1837

The host in welcoming his guests said he had chosen a date of great significance to the public health service. On that day one hundred years ago there had come into force the Act for Registration of Births, Marriages, and Deaths, on which the whole structure of our health services had been based. In the hope of finding evidence of the prescience of Parliament he had looked up the contemporary official reports of the debates on the Registration Bill. Unfortunately the speeches of Lord John Russell, Sir Robert Peel, and others gave no indication that legislators could foresee the ultimate effect of their Acts. The only reference to the public health implications of efficient methods of registration occurred in one short paragraph of the report which had prepared the way for the Bill. Happily Dr. William Farr was appointed under the Act as compiler of abstracts in the office of the Registrar-General, and his brilliant reports on the causes of death soon compelled attention. Liverpool led the way by appointing the first M.O.H. in 1847, and in the following year the City of London secured the great John

Simon. The other big towns quickly followed suit, and by 1856 provincial colleagues had founded the Society of Medical Officers of Health. Two years before this Sir John Simon had become the first Government medical officer; then followed the Public Health Act of 1872, which required each of over 1,400 urban and rural district councils to appoint a medical officer of health and a sanitary inspector. Finally in 1888 Lord Salisbury's Act created county councils with county medical officers. Thus, barely fifty years after the passing of the Registration Act the whole country had been covered with the essential staffing for health administration. With the development of these services and the extension from environmental to personal hygiene the creation of the Ministry of Health followed as a natural consequence in 1919.

Captain Elliston coupled his toast to the Society of Medical Officers of Health with the name of the President, Dr. Ernest Ward, who followed with an entertaining speech. Sir Francis Fremantle, M.P., proposed a toast to the *British Medical Journal* and the *Lancet*, coupling with it the names of Dr. N. G. Horner and Dr. Egbert Morland, and paid a tribute to the work and character of the late Sir Squire Sprigge. Sir Henry Brackenbury offered congratulations and thanks to Captain Elliston on behalf of the British Medical Association, which Sir Henry represents on the Council of the Society of Medical Officers of Health. Dr. James Fenton, president-elect of the Society, proposing a toast to Captain Elliston, spoke of the invaluable services he had given to the cause of public health as secretary of the Society for many years, as member of Parliament, and through the *Medical Officer*.

ROCKEFELLER TRAVELLING FELLOWSHIPS

The Medical Research Council has awarded Rockefeller Fellowships to the following for the academic year 1937–8:

Dermid Lockhart Cameron Bingham, M.B., F.R.C.S.Ed., Clinical Tutor, Surgical Out-patient Department, Royal Infirmary, Edinburgh.

Eric George Lapthorne Bywaters, M.B., Assistant Clinical Pathologist, Middlesex Hospital.

Philip Rainsford Evans, B.Sc., M.B., M.R.C.P., Registrar, Medical Diseases of Children, King's College Hospital, London.

John George Sclater, B.Sc., M.B., M.R.C.P.Ed., Tutor in Clinical Medicine, Royal Infirmary, Edinburgh.

Eric Frank Scowen, M.D., M.R.C.P., Assistant Director, Medical Professorial Unit, St. Bartholomew's Hospital, London.

Charles Herbert Stuart-Harris, M.D., M.R.C.P., Sir Henry Royce Research Fellow in Influenza, London.

Graham William Hayward, M.B., M.R.C.P., Resident Medical Officer, National Hospital for Diseases of the Heart, London.

All the Fellows propose to work at centres in the United States. Dr. Stuart-Harris and Dr. Hayward will hold their fellowships under modified conditions, while receiving emoluments from other sources.

In addition, the Rockefeller Foundation has awarded fellowships, on the recommendation of the Medical Research Council, to the following candidates in the special field of psychiatry, neurology, and related subjects:

Edward William Anderson, M.D., M.R.C.P., Medical Director, Cassel Hospital, Penshurst.

Alexander Kennedy, M.D., M.R.C.P., Assistant Medical Officer, Maudsley Hospital, London.

Alan Sutcliffe Kerr, M.B., F.R.C.S., Surgical Registrar, Royal Infirmary, Liverpool.

Denis John Williams, B.Sc., M.D., M.R.C.P., Resident Medical Officer, Hospital for Nervous Diseases, Maida Vale, London.

Alexander Francis Rawdon-Smith, Ph.D., Senior Student, Royal Commissioners for the Exhibition of 1851, working in the Psychological Laboratory, University of Cambridge.

Dr. Anderson proposes to work in Germany, the others at centres in the United States. Dr. Rawdon-Smith will hold his fellowship for six months only.

Reports of Societies

INFLUENCE OF EMOTIONS ON BODILY FUNCTIONS

At a meeting of the Section of Psychiatry of the Royal Society of Medicine on June 29, with Dr. T. A. Ross presiding, Dr. ERICH WITTKOWER of Berlin read a paper on "The Influence of the Emotions on Bodily Functions."

Dr. Wittkower said that the problem of psychosomatic interrelationships could be approached along various paths: his own investigations had been made along two—namely, the study of psychoneurosis linked to organs and the experimental production of psychical alterations and observations of the effect in the physical sphere. He left on one side changes in respiration and in pulse and blood pressure, as these had been considerably investigated by others. A strong emotional disposition reacted on the respiratory organs, even leading to permanent disorders of respiration. As for blood pressure, in pleasurable emotion the blood accumulated in the brain and at the periphery, and in painful emotion in the abdominal organs. His own experimental researches, carried out mainly under hypnosis, had been directed to fluctuations in the size of the heart as seen by *x* rays. The heart in common speech was supposed to be the seat of the emotions; persons were said to be soft-hearted, and cases of "broken heart" were recorded. The wife of one of his colleagues suffered from heart attacks during matrimonial arguments, and on one occasion her husband took an *x*-ray picture of her heart during an argument and found it distinctly smaller than normal. In other persons an enlargement of more than 1 cm. in diameter had been recorded.

Salivary and Gastric Secretion

Changes in salivary secretion, Dr. Wittkower continued, had been found in the particular person to be independent of the type of emotion experienced. Whether the emotions were pleasurable or painful the secretion would be found in one person to increase and in another to diminish. The influence of emotion on gastric secretion had been repeatedly investigated as to changes in acidity and quantity and emptying time of the stomach. Here again different emotions in the same subject always caused uniform changes. One subject to every kind of emotion reacted with hyperacidity, another with hypoacidity, one with a diminution and another with an increase of secretion. The form of reaction seemed to be typologically determined. He had come across certain cases in which there was a family tendency to diarrhoea on the occurrence of any nervous upset. He showed a family tree of twenty-eight persons of whom six suffered from "emotional diarrhoea." He mentioned another case in which an intense gastroptosis disappeared under psychological treatment (the case turned upon the rectification of a sexual difficulty).

Most emotions had a stimulating effect on bile secretion, but during annoyance the flow of bile was inhibited. He had an impression that the bile produced during joyous emotion was specially light in colour. Psychological factors might perhaps assist the onset of jaundice and even of gall-stones.

Urine Secretion

In some of the subjects examined under hypnosis no changes in the composition of the urine could be found in spite of strong emotion being provoked. In subjects in whom changes occurred these generally related most distinctly to quantity, total nitrogen content, and content of uric acid. In some cases a remarkable uric acid storage seemed to take place. A glance at an excited

person suggested a faint reflection of some of the signs seen in Graves's disease—protrusion of the eyes, palpitation, perspiration, and tremors. That the basal metabolism rose during emotion had been well shown, and a rise of blood-iodine content to values such as otherwise were only known in Graves's disease had been recorded.

Finally Dr. Wittkower described an attempt to make use of the psychogalvanic phenomenon in the affect-psychology of the healthy and of neurotics. This short review of the influence of emotions on bodily processes was bound to be incomplete. Emotion caused or was accompanied by a real disturbance of every bodily function, and emotional stress might therefore lead to serious disturbances and eventually to definite organic changes.

General Discussion

Dr. T. A. ROSS, from the chair, said that again and again patients were sent to the psychiatrist with the statement that, among other things, they were suffering from high blood pressure, but in fact on careful examination such high pressure was seldom found. The truth was that the doctor undertaking the first examination had upset the patient, leaving him in a state of doubt about certain things, and in that condition had taken his blood pressure, and inwardly thanked God that at last he had found a physical sign! It was interesting to learn that the reaction of the saliva and of the gastric secretion was the same for the individual—different for different individuals but not for different emotions in the same individual. If the history of these people were investigated it might be found that the direction of the reaction depended upon some accidental circumstance the first time it took place, and thereafter a repetition of any emotion caused the same type of phenomena to appear. The effect on the stomach had been a matter of age-long controversy. There were those who maintained that most indigestions were emotional; and, considering how many people were comparatively easily cured of dyspepsia by psychotherapy, it looked as if in large numbers of people dyspepsia was a neurosis. Some German work, based on *x*-ray observation, had contradicted this view, and had upheld the idea that the condition was a form of gastritis, but he noted that Alvarez, gastrologist to the Mayo Clinic, who began as a strong organistic physician, now said quite definitely that after twenty or thirty years of observation on the stomach he had come to the conclusion that cholecystitis was the commonest organic cause of dyspepsia, but that the commonest of all causes of dyspepsia was neurosis. Finally the speaker reminded his audience of the significant description in the Fifth Voyage of Sinbad the Sailor, how, when the ship on which he sailed was dashed to pieces, "the captain fell on the deck and tore his beard and his hair, and his gall-bladder was swollen with rage and with mortification"!

Dr. C. P. BLACKER asked how many patients were used by Dr. Wittkower in these experiments, whether they were selected as being patients in hospital or students or friends of the investigators, and what precautions were taken to ensure that they were normal members of the population. How were the emotions induced under hypnosis? Had he any standard technique for producing them? Did he detect any significant difference in the reactions of the patients according to age or sex? Dr. TRAVERS SMITH was surprised at the finding that the individual reacted in much the same way to different types of emotional stimulus. Might that be accounted for by the fact that anxiety was common to so many emotions? It would be interesting to know how far the experiment itself caused the emotion.

Professor DAVID SLIGHT pointed out some of the difficulties in such experiments—for example, the difficulty of getting adequate measures of registration, the difficulty of getting adequate controls, and the difficulty of inducing specific emotions experimentally. In some experiments in which he was concerned ten or eleven years ago in endeavouring to see how the effect of emotion could be recorded on the electrocardiogram he and those working with him had to confess that they could get very few changes at all. Their results were negative. As for the usefulness of the psychogalvanic phenomenon, this reflex or skin response was certainly an index of change in the emotional system, but unfortunately it was almost too sensitive, and his own results in this field had been very limited.

Dr. WILLIAM HEWETSON suggested that the greater prevalence of gastric ulcer at the present time was due to excessive worry and excessive use of tobacco. It was the long-distance effects which should be studied. Dr. RALPH NOBLE asked whether the opener had observed any relationship between emotional phenomena and blood disorders, even to the extent of pernicious anaemia. Recently he had seen a number of cases of neurotic patients who were suffering from that condition. Dr. D. N. HARDCASTLE had noticed that in the family tree shown by Dr. Wittkower the six persons who suffered from "emotional diarrhoea" were all females. Was there any difference between the sexes in this respect?

Dr. GERALD RUDOLF referred to certain cases some years ago in which he had injected adrenaline in large doses, and it was a common finding that from seven to fifteen minutes after the adrenaline had been used under the skin a sensation of fear developed. He thought there might be a link between the *p*H of the blood and the excessive secretion in the stomach. Dr. CLEMENT CHESTERMAN said that he had been working among the primitive Bantus in Africa, where emotions were quickly exteriorized. Among these people gastric or duodenal ulcer was extremely rare, and he had never come across a case of Graves's disease except in people who had had syphilis and suffered from hypertension. He had diagnosed one or two cases of diabetes which one was tempted to believe had some relation to an unstable nervous system.

Dr. LETITIA FAIRFIELD had noticed in a certain class of persons a difference in the incidence of nervous breakdown as between the sexes. Both male and female in a certain occupation were subjected to very much the same emotional strain, but breakdowns among the women of this class were very much more common, and it was suggested that the reason was that the men, when annoyed, could discharge their nervous energy by violent language or act, whereas convention forbade such a recourse in the case of the women. She wondered whether Dr. Wittkower had made any observations on a condition closely connected with neurosis—namely, hyperemesis gravidarum. Nowadays one never heard of neurosis in this connexion, but only of albuminuria and other disturbances of pregnancy. Might not the pendulum have swung too far?

Dr. MARGARET LOWENFELD said that it was very striking to note how frequently certain organic conditions in children were associated with extreme inhibition of emotion, but when, on treatment, emotion was released the physical symptoms diminished. She recalled a boy who, according to his mother, had never passed a solid motion. This intense fluidity of the intestinal contents was found to be associated with fear—a very mixed and confused fear in his own mind, of a sexual character. Without the use of any drugs or change of diet the release of the emotion and its expression in certain tangible forms was accompanied *pari passu* with a solidification of the bowel content. Another child had persistent constipation; this was a very shy and timid child, and well-directed psychological treatment, the encouragement of a frank expression, and direct discharge of emotion resulted in the steady clearing up of the condition. Another child of 5 had had an almost uninterrupted stay in hospital with one infectious disease after another, with intervals of bronchitis and dyspepsia. The child was thin, debilitated, completely inhibited, suggestive of a moron, but after a period of play treatment for eighteen months

she had attained normality in weight, general appearance, and expression.

Dr. WITTKOWER, in reply, said that his experiments had been carried out over a period of ten years, and of course the subjects were changed from time to time. The subjects were either patients who had been successfully treated or they were students. It was quite easy to produce emotions under hypnosis. Knowing the history of these people he could produce a specific effect of joy or grief. A considerable increase in the leucocyte count was found under emotional influence. He had had no experience of hyperemesis gravidarum, and in this and in other respects he was fully aware that his findings were incomplete, but he would have the opportunity to continue his studies at the Tavistock Clinic.

BLACKWATER FEVER

A meeting of the Royal Society of Tropical Medicine and Hygiene was held at Manson House on June 17, with the new president, Colonel S. P. JAMES, F.R.S., in the chair. A conjoint paper on blackwater fever in Macedonia was presented by Mr. HENRY FOY and Dr. A. KONDI, and this was followed by one by Dr. N. HAMILTON FAIRLEY and Mr. R. J. BROMFIELD on pseudo-methaemoglobin in blackwater fever and its clinical significance.

Blackwater Fever in Macedonia

Mr. Henry Foy stated that during five years' work in Greece he and Dr. A. Kondi had investigated some 450 cases of blackwater fever in the laboratory. These cases were drawn from the Refugee and Municipal Hospitals in Salonika, the villages and towns in the Plains of Drama and Chrysoupolis, and from Northern Peloponnesus. The disease was particularly prevalent in the Vardar plain and the Struma valleys. When it was remembered that probably not more than 20 to 25 per cent. of cases reached hospital, the magnitude of the problem was evident. From 1923 to 1935 the average monthly admissions of malaria had been 1,779, and for blackwater fever 58.7. Blackwater fever was most frequent from September to January. The two-monthly lag that had already been observed by other workers was present in Macedonia, for the peak of blackwater fever appeared in November, and that for malaria in September and October. Throughout the period the percentage of malaria that was blackwater averaged 3.297. The low incidence of blackwater fever and malaria in 1923 and 1924 was no doubt related to the immigration of large numbers of non-immune refugees from Asia Minor in those years.

As a result of mathematical analysis of the available data, Mr. Foy said, it was perfectly clear from their regression equation that (1) the number of blackwater fever cases in any one year was quite independent of the number of malaria cases either in the previous year or the previous two years; (2) in a population that had already been exposed to malaria for one or two years the number of cases of blackwater fever was significantly correlated with the number of malaria cases of the same year; (3) this correlation did not appear to hold in an unsensitized population, no matter how severe the malaria. Another point which emerged from their figures was that the susceptibility of the population of Macedonia to blackwater fever had been increasing with time, although somewhat irregularly, and that it was gradually working towards an upper asymptote, when the "blackwater-producing capacity" of malaria would become stable. Regarding the parasite rate in blackwater, they had found approximately 40 per cent. of their cases positive, taking as their criterion any case showing parasites up to within fifteen days after the first passage of black urine. The rate was no doubt low on account of the large number of cases that took quinine just before the attack. The positives among 360 cases were 47 per cent. *Plasmodium falciparum* and 33 per cent. *P. vivax*; the remaining 20 per cent. were either quartan or mixed. Ruling out quartan as a producer of blackwater fever and compensating for the improved diagnosis of subtertian malaria, their figures indicated that *P. vivax* and *P. falciparum* were both producers of blackwater fever, and that, contrary to accepted teaching, *P. vivax* was the more potent. This conclusion was consistent both with the regression coefficients which they had found and with the actual parasite rate.

Pseudo-methaemoglobin in Blackwater Fever

Dr. Hamilton Fairley said that in 1934, in conjunction with Mr. R. J. Bromfield, he had described a new blood pigment encountered in the plasma of a severe case of blackwater fever in London, and that a year later they had demonstrated it in another similar case. In November, 1936, under a grant from the London School of Hygiene and Tropical Medicine, they went to Salonika, where Mr. Henry Foy generously afforded them laboratory and clinical facilities for the investigation of this problem. Some twenty-five cases of blackwater fever were personally investigated in hospitals in Salonika and adjacent villages during a period of six weeks, which illustrated the unique potentialities in Macedonia for the study of this disease.

As a routine procedure the plasma and urine were examined on a Hartridge spectroscope set against artificially produced methaemoglobin, and the effects of treatment with Stokes's reagent, ammonium sulphide (10 per cent.), and hydrogen peroxide (10 vols.) were noted. All these reagents dispersed the α band of true methaemoglobin, but not that of the new pigment. In special cases the effect of treatment with sodium hydrosulphite was also determined.

Fourteen cases were investigated in detail. The plasma contained oxyhaemoglobin alone in two mild cases, new pigment alone in two severe cases seen on the third and sixth days respectively, and new pigment and oxyhaemoglobin in the remaining ten. In not a single instance was methaemoglobin demonstrated. From these findings it was evident that all previous workers who had described methaemoglobinaemia in blackwater had really been observing the new pigment, for which the name pseudo-methaemoglobin was now suggested. The urine, on the other hand, never contained pseudo-methaemoglobin in demonstrable quantity. Oxyhaemoglobin was found alone in two instances, and in association with methaemoglobin in ten others; in the two remaining cases the urine contained no blood pigments, though pseudo-methaemoglobin was in the plasma. All available data indicated that, unlike oxyhaemoglobin, the new pigment was a non-threshold substance for the kidney, and that urinary methaemoglobin was derived from oxyhaemoglobin only during or after its passage through the tubules.

The formation of methaemoglobin in sterile blood or haemoglobin solution stored under ordinary conditions or after incubation at 37°–55° C. had long been recognized. To ascertain whether the new pigment could be produced *in vitro*, 4 vols. of sterile plasma from blackwater fever patients were incubated at 37°–40° C. for forty-eight hours with 1 vol. of a concentrated solution of haemoglobin prepared under aseptic conditions from laked corpuscles. Pseudo-methaemoglobin was invariably produced. But, contrary to expectations, when normal plasma was used as a control the new pigment and not methaemoglobin appeared. Pseudo-methaemoglobin was also formed when a solution of artificially prepared methaemoglobin or sulphaemoglobin was incubated with plasma at 37°–40° C. for forty-eight hours. On incubating a solution of oxyhaemoglobin alone, methaemoglobin was invariably formed. These experiments proved that plasma had the power of converting extracorpuscular haemoglobin, methaemoglobin, or sulphaemoglobin into the new pigment when incubated under appropriate conditions.

Pseudo-methaemoglobin contained trivalent iron, and, like methaemoglobin, could not function as a respiratory pigment. It produced a brown-coloured plasma, but was never found within the corpuscles and did not appear in the urine in demonstrable quantity. Its production from extracorpuscular circulating oxyhaemoglobin was a conservative action on the part of the body, since the kidneys were protected from the blockage of the tubules which resulted from the elimination of oxyhaemoglobin in acid

urine. Its formation appeared to be the first stage in a process by which the body disposed of circulating extracorpuscular pigment, and the formation of pseudo-methaemoglobin might be anticipated in any intravascular haemolysis of sufficient magnitude and duration. Since 1864, when Hoppe-Seyler first described methaemoglobin, this pigment had escaped recognition through being consistently confused with methaemoglobin. For this reason the name "pseudo-methaemoglobin" appeared a not inappropriate one.

Discussion

Sir RICKARD CHRISTOPHERS said that both papers broke much new ground. The remarkable figures which Mr. Foy presented regarding the monthly incidence of the disease in Macedonia made this an ideal place to investigate the blackwater fever problem. The new pigment must be of considerable practical importance, and it was of special interest in blackwater as its presence and spectroscopic insensitiveness accounted for the underestimation by previous workers of the total amount of blood destroyed. It, however, threw no new light on the cause of the haemolysis. To the European blackwater fever was the most important of tropical diseases. It gave to Africa the name of "the white man's grave," and prevented the colonization of new areas and many commercial and economic projects.

Professor WARRINGTON YORKE pointed out that the death rate from blackwater fever in Rhodesia had shown no improvement since 1900. Dr. Fairley had explained that evening something which had been very puzzling to himself and all other workers—namely, why the oxyhaemoglobin in the plasma was so small in amount. The speaker had proved that only 10 per cent. of the blood destroyed was eliminated through the kidneys. This, according to Dr. Fairley, was due to the transformation of oxyhaemoglobin into pseudo-methaemoglobin, which was not secreted by the kidney. In other diseases, like babesia, there was much more free oxyhaemoglobin in the plasma than in blackwater fever, and he wondered whether previous hypertrophy of the reticulo-endothelial system might account for the discrepancy. In association with Norris he had also produced evidence that oxyhaemoglobin was secreted by the tubules rather than as a transudate through the glomeruli. He agreed with everything Sir Rickard Christophers had said regarding the importance of blackwater fever in the Tropics, and hoped that every encouragement would be given to Dr. Fairley and Mr. Foy to prosecute their studies in Macedonia.

Professor DE KOCH discussed the allied problem of epizootic icterus in sheep in South Africa. The aetiology was obscure, but the disease was associated with methaemoglobinuria and great blood destruction. Peculiar pigment reticulum cells were found in different organs, and the liver contained a higher percentage of copper than normal. Dr. C. C. CHESTERMAN asked Mr. Foy if quartan malaria in some way gave immunity to blackwater, and whether in his cases of *P. vivax* infection he was not dealing with mixed infections. Major J. S. K. BOYD stated that in his experience in Macedonia during the war every case among the British troops was potentially one of mixed infection. Although one species might be demonstrable in the blood at the time of haemoglobinuria, both parasites had at some time been present.

In reply, Mr. FOY said he could not explain the absence of quartan parasites, but the findings were equally negative whether splenic smears or peripheral blood were examined. Their experience had been that before the onset of blackwater fever the spleen was not loaded with malaria parasites. The parasite rate itself was of little significance in blackwater since it depended on the time and amount of quinine taken prior to onset, the degree of haemolysis as measured by red cell counts, and the interval between the onset of haemoglobinuria and collecting the blood.

Dr. HAMILTON FAIRLEY, in reply, stated that pseudo-methaemoglobin had nothing whatever to do with the fundamental cause of haemolysis in blackwater fever, though it did throw light on subsequent events once haemolysis started. He did not share Professor Yorke's pessimism that nothing could be done therapeutically in blackwater fever. Their clinical and pathological studies in London and Macedonia revealed two types of patient: one dying of anaemia with polyuria and adequately functioning kidneys, the other succumbing to anuria and uraemia. The former could be saved by multiple blood transfusions. Alkalization of the urine was a rational procedure, and the work on pseudo-methaemoglobinaemia entirely supported the experimental findings of Baker and Dodds that methaemoglobin was produced in the tubules, and that there was less "silting-up" effect in the presence of an alkaline urine. In incompatible blood transfusion a pigment occurred with an alpha band in the red spectrum resembling that of methaemoglobin. As a result of *in vitro* experiments he predicted that this pigment would prove to be pseudo-methaemoglobin.

Local News

ENGLAND AND WALES

Medical Art Society

This year's exhibition of the Medical Art Society, held at the Royal Society of Medicine, 1, Wimpole Street, is one more example of the versatility of the medical profession. The general level of the work is very high, but on the whole the water-colours are perhaps the most successful. "Farm Track, Breconshire," by J. F. Robinson, is a very pleasing snow picture, and "A Study of Trees" by the same artist also well repays study. John Hay shows great ability in handling colour and design in "The Cheviots, near Wooler" in oil, and "The Copper Beech" and "St. Ives" in water-colour. "The Chalk Bank" by Charles Pannett is pure in colour and good in drawing and design. R. Hallam shows three lively and amusing sepia sketches: "The Orchestra," "Flower Sellers," and "The Discussion." The pencil sketch "The Lone Tree in Norway" by Humphrey Neame is delicate and decorative. Among many other charming water-colours are "Marram Hills, Norfolk" by E. B. Waggett, "Morston Staithe" by Henry Wilson, "Railroad, New Forest" by Dorothy Hare, "Straits of Messina from Taormina" and "Bou Sada, Algeria" by R. Foster Moore, and "Allotments in Winter" by H. B. Maitland. "Sable Antelope" (tempera) by A. C. Dalzell is a good piece of design. We see here in this exhibition further proof of the versatility of the late Sir Squire Sprigge in his four charming water-colours "Golden Spring," "The Pond," "New Forest Trees," and "Mountain Spring near Bad Gastein." Among the oil paintings "Ship in Distress, Tintagel" is a wonderful representation by A. S. Cobbledick of a storm off the coast of Cornwall. Special attention should also be drawn to the two pictures painted at Walberswick by John Rammell; to "Punta Espada, Pyrenees, Cataluna" by John Rammell; to "Reflected Ramparts, Marra Kech" and "An Olive Grove" by Helena Wright; to "Kingston Harbour, Jamaica" by Leonard Colebrook; and to the "Landscape with Figures" and "Old Village Road, Belgium" by Allan Beale Hewlett. There are also several successful portraits by A. S. Cobbledick, H. Elliott Blake, R. V. B. Emmons, and H. B. Maitland. Among the flower paintings are two delightful screens by Sir Leonard Hill; Emanuel Miller's "Flower Piece" is very successful, and so are the chrysanthemums by W. Wilson and the Christmas roses by Cuthbert Lockyer. There is also some interesting sculpture; the standing figure by L. Spira is virile and

well balanced, and the plaster casts "Rest" and "The Diver" by E. S. Tait are rhythmical and pleasing. The flower studies by Arthur Edmunds in silver filigree and enamel are most decorative. The exhibition will remain open each day (Saturdays excepted) from 12 noon to 6.30 p.m. until July 14. Admission is free without ticket.

University of Durham Centenary

The centenary celebrations of the University of Durham, postponed from 1932, were held last week at Durham and Newcastle-upon-Tyne. Former students from various parts of the country spent the morning of Thursday, July 1, in visiting the Castle and the College at Durham, and at noon attended a service in the Cathedral, at which the Bishop, Dr. Hensley Henson, was the preacher. In the afternoon the honorary degree of D.C.L. was conferred by the Chancellor, Lord Londonderry, on a number of distinguished men, including Sir Cuthbert Wallace, Bt., President of the Royal College of Surgeons of England. Luncheon parties were held in the great hall of University College, with the Vice-Chancellor, Sir Robert Bolam, in the chair, and at the Town Hall, where Lord Londonderry took the chair as Mayor of Durham. On Friday, July 2, the celebrations were continued in Newcastle at the College of Medicine and Armstrong College.

St. Mary's Hospitals, Manchester

In the report for 1935 of the maternity department of St. Mary's Hospitals, Manchester, Dr. E. A. Gerrard analyses 3,294 cases attended during the year. In-patients numbered 2,374, and 920 patients were delivered in their own homes. There were thirty-one maternal deaths, eight in "booked" cases and twenty-three among the emergency cases, representing a mortality of 0.76 per cent. of the total in-patients, while the mortality in all "booked" deliveries, including the "district" cases, was 0.4 per cent. The morbidity rate, estimated by the British Medical Association standard, was 5.9 in "booked" cases and 7.6 in emergencies. Of the 157 cases showing puerperal morbidity, forty-three had Caesarean section and thirty-eight had normal labours. The cause of the morbidity was puerperal sepsis in no less than 101 of these cases. The maternal mortality in 112 breech deliveries was 1.6 per cent. and the foetal mortality was 41 per cent. Corresponding figures for sixty-two cases of placenta praevia were 6.3 and 33.8 per cent. Of 234 cases of abortion, the process was incomplete in 102, inevitable in seventy-seven, and therapeutic in forty-four. In these last cases abortion was induced on account of phthisis in thirteen cases and cardiac insufficiency in seven. Classical Caesarean section was performed in sixty-five cases, and the lower segment operation in seventy-seven cases.

One of the aims of the British Health Resorts Association is to make more widely known the medical climatology of British coast resorts, and in pursuance of this aim a special chapter on climatology by a recognized expert is included in the latest (1937) edition of *British Health Resorts*, the association's handbook. In reply to questionaries issued in 1935 and 1936 the Association has collected some interesting reports on the "invalids winter" on the coast, and from these a valuable analysis of the atmospheric conditions from month to month has been prepared. The handbook also includes a synopsis of the attractions afforded by British resorts during the "invalids winter." To the section dealing with health resorts in the Dominions and Colonies has been added information concerning the island of Cyprus. The whole of the material has been carefully revised by an expert subcommittee of the association. Altogether a most valuable handbook which no medical man can afford to be without.

Correspondence

Tubo-uterine Implantation for Sterility

SIR,—I have read with interest Mr. Green-Armytage's excellent paper in the *Journal* of July 3 (p. 6) on tubo-ovarian implantation, and I thank him for his handsome reference to my work.

I began to do the operation in 1921, and naturally have changed my technique from time to time since then. Latterly I have adopted a method which, I think, renders the passage of silkworm gut down the implanted tubes unnecessary. It has been urged against tubo-uterine implantation that the new internal ostia do not remain patent, and, having regard to the small calibre of the isthmic segments, it is obvious that very little would be required to close them. The placing of strands of silkworm gut in the implanted tubes is done to prevent this. The ampullary segments of the tubes, on the other hand, have a much larger calibre, and post-operative closure of the new internal ostia is much less likely if, after cutting away the whole of the isthmic segments, these segments be implanted. This is what I have been doing for some time now.

It raises the question, For what purpose does Nature form the isthmic segments? Why do the ova have to traverse such long and narrow passages? It may be suggested that the purpose is to delay the entry of the fertilized egg-cell into the uterus until the capsule that envelops the early cell divisions has disappeared and the cell mass is free to attack the surface of the endometrium. If this was so, then an egg-cell that entered the uterus too soon after fertilization would fail to graft. The many recorded cases in which intra-uterine pregnancy has occurred after removal of both tubes down to the uterine cornua directly negative this, while primary ovarian gestation shows that for the purpose of pregnancy it is not necessary for the egg-cell to traverse the tube at all. It is believed that ordinarily the sperm blends with the egg-cell in the tube. Whether blending ever occurs in the uterus, or, occurring there, is followed by grafting, is unknown; but the cases to which I have referred suggest that it may very well happen.

Of the various causes that bring about blockage of the tubes there is one that is of particular importance in this connexion—namely, congenital impatency. These cases are far from uncommon, and in most of them (but not all) the uterus is smaller than normal. It is often described as "infantile," and the patient's sterility is ascribed to her small uterus—the fact being forgotten that pregnancy can occur in the far smaller Fallopian tube. The real cause of the sterility in these cases is a congenital lack of patency of the tubes, which an operation reveals to extend along the whole length of the abnormally thin isthmic segments. In such patients the surgeon *has* to implant the ampullae, as he also has to do in those cases in which a previous salpingitis has produced the same condition.—I am, etc.,

London, W.1, July 3. VICTOR BONNEY.

Present-day Methods of Sterilizing Dressings

SIR,—Dr. M. J. Oliver, in his letter published in the *Journal* of May 22 (p. 1089), confirms my opinion that the process of dressing sterilization leaves much to be desired. My impression is that manufacturers are aware of the facts and literature quoted by Dr. Oliver. They

lay great stress on the preliminary expulsion of air before exposing the dressings to steam, and presumably design sterilizers accordingly. The Grampian Engineering Co., Stirling, issue an interesting booklet containing the conclusions of most of the workers mentioned by Dr. Oliver.

My experiments were conducted on sterilizers of first-class make, with the object of proving their efficiency according to a bacteriological standard, which may possibly be regarded as too high, and when using them in accordance with the manufacturers' instructions. After verbal conversation with the manufacturers, and after reading their literature, I accepted the fact that all air was expelled providing the instructions were followed. Five sterilizers were tested by control tubes and were found to be inefficient. Four were tested with the electric control, and only one—of Indian manufacture—was found to be efficient. (Group IV Exp. Vacuum Hospital B.) The publication of all the experiments was curtailed owing to lack of space.

If it is accepted that the discrepancies in these experiments and in those of other observers are due to air contained in the dressings, it is clear that: (1) either the sterilizers tested are inefficient or the working instructions are incorrect; (2) my statement that the electric control provides absolute safety is incorrect, as under the above conditions it could only indicate when the temperature reaches 115° C.; (3) the conclusions to be drawn from the experiments made are worse than at first thought. As dressing sterilization is carried out in a closed machine, and as there are so many pitfalls in the technique, I suggest that it is logical to ask for proof that the contained air in dressings is driven off, and that steam penetrates through the contents of the dressing containers. Until this is done we cannot accept the process as satisfactory.

Dr. Oliver points out an error in my statement "dry, saturated, or moist steam." Through an error in typing commas have been inserted after "dry" and "saturated." —I am, etc.,

S. N. HAYES,
Major, I.M.S.

Kashmir, June 18.

The History of Surgery

SIR,—Although it is as true to-day as in 1894, as Osler then stated, that "we are even impatient of those who would recall the past and would insist upon the importance of its recognition as a factor in our lives, impatient as we are of everything save the present with its prospects, the future with its possibilities," it is equally true that "in a continual remembrance of a glorious past, individuals and nations find their noblest inspiration." It is perturbing, therefore, to one who is an examiner in several universities to find that many candidates for degrees in surgery lack the barest knowledge of those members of the mighty dead who have made the great contributions to their subject. Candidates who successfully ligature the femoral artery in Hunter's canal when called upon to do so, and who show an accurate knowledge of the surgical anatomy, not infrequently lack all knowledge of who Hunter was, and, incredible though it may seem, I have even met students to whom Lister's name was a blank. The sad thing is that to such men there can be little or no romance in their subject. The fault appears to lie early on in the student's career. In the amassing of a wealth of detailed knowledge of anatomy and physiology and related subjects he may well lack the time and energy to pursue independent investigations as to what manner of men were the contributors whose names are mentioned in his textbooks. The foramen of Magendie, Poupart's ligament, the bundle of Vicq d'Azyr, are to him a foramen, a ligament, and a strand of nerve fibres respectively.

"A primrose by a river's brim,
A yellow primrose was to him,
And it was nothing more."

If, however, the writers of his early textbooks would only publish, however briefly, a few small-type footnotes referring where they appear in the text to the men whose names are household words, the student would, I believe, be helped not only by the addition of some human interest to what may possibly be dry-as-dust material, but also by the production of an association of ideas which would assist his memory of detail.—I am, etc.,

LAMBERT ROGERS.

Cardiff, July 1.

Technique in Knee-joint Operations

SIR,—It would be nice to know whether skin towels are a shibboleth or a sheet-anchor. Perhaps the question is best viewed from three aspects: (1) their efficacy in preventing inoculation of the subcutaneous fat with subepithelial organisms; (2) their efficacy in preventing contact between gloves, instruments, and suture material with the skin surrounding the operation wound; (3) the duration of surface sterilization resulting from preparatory dressings.

In a previous communication I suggested that they were not only useless but positively dangerous, inasmuch as they rapidly become damp and smear organisms into the deeper parts of the wound. I advocated as a substitute the antiseptic method which I learned from Mr. Naughton Dunn, and which he still practises, according to his letter in the *Journal* of July 3 (p. 34). The second aspect presumably depends on the duration of the operation, the permeability of the skin towels, the dexterity of the operator, as well as on the particular method of preparation used for the skin. The third point has probably been investigated, but I have no references.

There are two ways in which the question might be settled: (1) by comparison of operative results done by different methods (Cotton's "end-result idea"—see preface to his book, *The Shoulder*—points the way, but in our present unenlightened state we have no figures); (2) by experimental bacteriological work carried out during routine operations under different conditions.

Mr. Blundell Bankart, in your issue of June 12 (p. 1227), does not follow either method, but presents his opinions as facts. He assumes that stitch abscess must always be due to infected catgut, and that the infection occurs from the skin. I submit that both these are unproved, since catgut can be infected in many ways and a sterile abscess may even result from over-hardened suture material. His second assumption—that because I advocate a different technique I must therefore get more stitch abscesses than he does—is charmingly uncharitable. Surely one may give a list of post-operative complications without having one or all of them wished off upon oneself?

I fear that until such time as the "end-result idea" becomes something more than an idea, or until the bacteriologists do some fresh work on this subject, we shall continue to confuse our shibboleths and sheet-anchors.—I am, etc.,

ERIC I. LLOYD.

London, W.1, July 2

Treatment of Rheumatic Conditions

SIR,—From the physiological point of view it is, I think, likely that the movements of stiff and painful joints carried out by the patients themselves but guided by skilled nurses are of more benefit than massage when given after treatment by heat, light, or electricity. A great deal of time and labour can be saved by substituting exercises for massage. The greater benefit of exercises is attested to by a colleague experienced for many years in treatment of rheumatic cases by methods of physical medicine.—I am, etc.,

St. John Clinic and Institute of Physical Medicine, June 30. LEONARD HILL.

Prevention of Constipation

SIR,—I am surprised that the correspondence on the prevention of constipation has not produced any reference to the early initiation of the human body into the pernicious practice of purgation. My own thoughts on the subject were crystallized by an admirable monograph by Dr. L. G. Housden—*The Breast-Fed Baby in General Practice*—a Sir Charles Hastings Prize winner.

Almost every breast-fed baby causes concern during its first few months of existence on account of "constipation"—that is, infrequent bowel motions. The absence of residue in its diet and the frequency of slight underfeeding lead the child to empty its bowel at widely spaced intervals, especially in these days of zealous regimentation, when infants are fed on calories, minutes, and ounces.

When I am told that a healthy breast-fed baby is "constipated" I ask whether the motion is hard or normal. If it is hard I know that purgatives have already been given. If it is normal I explain to the mother that the baby is not constipated, and warn her against any interference with the natural bowel function such as is certain to be urged by her friends. I have many records now of babies who have for a time, often extending up to weaning, had their bowels moved even at such infrequent intervals as a week, and not one has ever had constipation or subsequently developed it. Many of these children have never had a purgative in their lives, and the maternal pride when weaning brings three motions a day is gratifying if amusing. Often the crying of a slightly underfed baby is attributed to the infrequency of the bowel evacuation; purgation follows, and depletes it still further. In an effort to retain its fluids the body extracts more water from the intestine, and true constipation results, and is followed by further purgation.

The old practice of giving babies castor oil even on such flimsy pretexts as to get rid of the meconium is dying out, but there are still attendants who derive great "kudos" from curing icterus neonatorum by means of grey powder. Indeed, almost any excuse to give a purgative is seized, and life-long addiction may result.

The healthy breast-fed baby whose bowels move once a week needs an occasional drink of water and nothing more.—I am, etc.,

Newcastle-upon-Tyne, June 27. FRANK STABLER.

Toxic Focus with Ophthalmic and Dermic Reactions

SIR,—Trying to find an elusive toxic focus is so often tedious and unfruitful, despite the greatest perseverance, that some of your readers may be interested by an account of a successful case in which there were two types of reaction—ophthalmic and dermic. Probably in many of the unsuccessful searches investigations are started when the original focus has already cleared up, though the results of the damage done elsewhere are still evident.

A married woman, aged 32, was first seen by me in June, 1936. In 1911 she had had scarlet fever; in 1919 and in 1926 erythema nodosum of both legs; in 1926 psoriasis on the back, arms, knees, and scalp, which resisted treatment; and in 1932 episcleritis in the right eye.

When I first saw her I found her to be suffering from episcleritis in both eyes and psoriasis on her back, arms, knees, and scalp. She appeared to be in good general health. The episcleritis responded to treatment and cleared up, but at the end of September she developed a fresh attack in the right eye, which improved under treatment before relapsing and developing into scleritis with iritis.

By the middle of October iridocyclitis supervened with a profuse keratitis punctata. These cleared up but left an area of sclerosing keratitis, with vascularization at the corneal margin. During this time she had a slight scleral inflammation of the left eye which responded to treatment and was cured within a few days. Taking into account the history, the prognosis was grave, and serious loss of vision might be anticipated ultimately unless the active focus could be definitely found. All investigations had proved fruitless; the Wassermann reaction was negative.

The condition of the teeth and gums did not arouse suspicion. She had recently attended a dentist, but a further dental opinion suggested that some of the teeth which showed a mild chronic condition might be worth investigation. A tooth was extracted and a culture made from the root and socket. This showed a profuse growth of *Streptococcus viridans*. As part of the routine treatment an autogenous vaccine was given. Further extractions were done; the teeth exhibited apical infection.

No further inflammatory reaction has since occurred in either eye, and the corneal opacities resulting from the sclerosing keratitis are fading. Vision is now full (6/5) in each eye.

The patient has put on weight, and looks very well. The skin conditions, which previously had run a chronic course resisting treatment, are now showing very satisfactory progressive improvement. I feel that sufficient time has elapsed for us to assume that the cause of her troubles was located and eradicated. I am indebted to Dr. Hardy Kingston and to Mr. Jacobs for their help in this case.—I am, etc.,

Bristol, June 30. J. EDWARD MARTIN, Honorary Surgeon, Bristol Eye Dispensary.

Ionization for Hay Fever

SIR,—In the correspondence on this treatment two subjects have been discussed: hay fever, which is seasonal, and paroxysmal rhinorrhoea, which is not. In the former allergy plays the major part; in the latter a less obvious one. For hay fever I have abandoned desensitization for zinc ionization by Mr. Philip Franklin's method. It is simpler, less costly, and more effectual, but it requires meticulous care in application. I have had few failures, and have rarely had to give more than one treatment during the season. But in addition it is always worth while to stop milk during the season and to give calcium gluconate or lactate. Some fibrinous exudate is troublesome for the first few days after treatment, but it is probably this and weakened ciliary action that explains the benefit, the entry of pollen protein into the blood being lessened or prevented. At all events the rhinorrhoea diminishes or disappears, though the eosinophilia may remain high. American writers have imputed permanent ciliary damage to ionization. Such damage I have not seen, though it may conceivably happen from over-treatment. The nose of a doctor treated success-

fully last year was quite normal when he returned for treatment before the beginning of this season.

For paroxysmal rhinorrhoea ionization is mostly futile and the cautery often harmful. The late Dr. Arthur Hutchison of Brighton many years ago sent me a relative, aged about 50, who had been troubled with paroxysmal rhinorrhoea for the great part of her life and had had cauterization and other treatment from himself and colleagues in London. The condition promptly cleared on her taking calcium gluconate. One form of this affection is on the increase since the present vogue of *raw* milk for school children began. This "milk rhinorrhoea" promptly stops with stopping of the milk, and will not stop otherwise. This I have proved over and over again, and it can be verified by anyone who tries it. Whether this is a form of allergy I am not here going to discuss, beyond repeating what I have often said: that while milk is *the* food for babes man is the only animal that takes it after weaning, and that, although it contains no histidine, it is apt, as Koessler and Hanke showed, to promote the formation of histamine in the intestine provided certain coliform bacilli and an acid locus are also present.

Most cases of paroxysmal rhinorrhoea will clear up if four points are observed: (1) milk stopped; (2) an open-air life followed; (3) calcium gluconate or lactate given daily, together with cod-liver oil and malt extract and perhaps parathyroid; (4) a mercurial given weekly. Is there, for some forms of allergy at all events, a better desensitizing agent than a regular blue pill? For, as Mr. Frank Coke hints, whether the antigen is inhaled, as in hay fever, or ingested, as in some forms of vasomotor rhinitis, there is a general condition, a soil, which renders the individual prone to allergy, and the general measures I have indicated help to alter this. The interesting question is left with regard to these nasal affections and to asthma—Why should the respiratory tract be the favourite route for the "excretion" of histamine and eosinophils? —I am, etc.,

Glasgow, July 3. JAMES ADAM.

Excitability

SIR,—Your editorial on the action of acetylcholine on the central nervous system (May 29) requires further notice. Some time ago I collected together in my book *Excitability* the evidence of fact from which one could deduce the laws that govern the natural stimulation of beating hearts, and know their modes of behaviour when so stimulated. Up to that time, it should be noted, physiologists had only investigated the unnatural electrical excitation of cardiac muscle, and that usually in the unnatural state set up by a Stannius ligature. In some medical schools those artificialities still pass muster as the "properties of heart muscle."

In my book I also point out that the reactions of living nervous structures in the body to their natural stimulation were precisely the same as those of beating hearts when stimulated by hormones or drugs. Evidence concerning the latter not then being available, I had to leave matters at the point of formulation of a new doctrine of the inherent rhythmical activity of structures in the living body.

Such ideas were then strongly condemned by your own expert in physiology because they were "in defiance of all the established canons of physiological thought." Undoubtedly they then were. Your editorial indicates, however, that what was then a heresy is now on the way to graceful orthodoxy—a not unusual state of affairs in medicine. I may also mention that some of my predictions concerning how living neurones must act have been brilliantly confirmed by Professor Adrian of Cambridge. I mention that to fortify the opinion that investigators of these matters will not be able to evaluate their facts adequately until they learn how *beating* hearts react to natural stimulation.—I am, etc.,

King George's Medical College, Lucknow, June 20. W. BURRIDGE.

Electromedical Equipment and Radio Interference

SIR,—It has come to my notice that the British Standards Institution has formed a subcommittee for investigating the possibilities of suppressing radio interference due to electromedical equipment. I am not in a position to state what the terms of reference of this subcommittee are, nor do I know of its exact constitution. I have, however, been able to ascertain that although such a body as the British Institute of Radiology is represented the medical profession as such is not.

It seems to me that if the interests of those who employ the apparatus are to be safeguarded the British Medical Association should be represented by two members of the British Medical Association. In my opinion these should be a member of the Physical Medicine group, preferably an electrologist, and a surgeon, again preferably one who is alive to the importance of the application of diathermy in surgery.—I am, etc.,

London, W.1, July 1. PH. BAUWENS.

What is Osteopathy?

SIR,—As my brother, Dr. Kelman Macdonald, is at present in America, and therefore unlikely to see and be able to reply to Sir Ernest Graham-Little's letter in your issue of June 26, I shall be most grateful if, in his absence, you will allow me to reply on this occasion. I would particularly like to point out that I do not want to enter into this discussion on my own account, as the arguments that have been brought up are already sufficiently complicated. I ask to be allowed to reply more particularly in view of the fact that Sir Ernest's letter not only contains one serious misstatement of fact but is otherwise liable to create misunderstanding.

Surely Sir Ernest and his medical colleagues are more concerned with public safety in the future than with "old, unhappy far-off things." It is, therefore, to use his own expression, "idle" for him to go on saying that the British Osteopathic Association gave its "fullest sanction and support" to the British School of Osteopathy—it is surely of greater importance that the B.O.A. is not officially represented on the Governing Board of the School. But it is more than idle, it is positively inaccurate, for him to say that the British Osteopathic Association has not begun to comply with the present Prime Minister's requirement that it should establish reputable educational facilities. Really Sir Ernest, if he is going to indulge in public controversy of this nature, might do his opponents the courtesy of acquainting himself first with the facts.

The British Osteopathic Association examined the position thoroughly in its special College Committee, and in 1935 a limited company was registered called Osteopathic Trusts, charged specifically with the task of establishing a college and hospital which would conform in curriculum and equipment with the requirement referred to by Sir Ernest and with the standards stipulated by the General Council and Register of Osteopaths. This body now employs a full-time official who is engaged on a plan

of campaign, and the profession has further applied itself to the difficult problem of the provision meanwhile of adequate post-graduate training for those osteopaths whose previous training is not held by the General Council of Osteopaths to qualify them for the Register. It surely ill becomes Sir Ernest Graham-Little and those who think with him to taunt us with the accusation of doing nothing when we are merely taking that reasonable care which he has been accustomed to imply has been the distinguishing mark of the orthodox school.

If Sir Ernest cares to read Sir Robert Stanton Woods's presidential address, from which my brother quoted briefly, he will find there that Sir Robert differed strongly from him with regard to at any rate one of the six important schools. I will not take up space by quoting the actual words.—I am, etc.,

London, W.1, June 29. GEORGE MACDONALD.

Air Raid Precautions

SIR,—Dr. Colquhoun's suggestion in the *Journal* of June 26 that there should be established a medical committee to go fully into the measures adopted by the Government to protect the public against the effects of air raids is a good one, for many reasons. It would interest a large section of the medical world in the details of the present air raid precautions scheme; it would refute the destructive criticisms of medical members, many of whom, one feels, have not got first-hand information on the subject, or who, perhaps influenced by pacifist ideals, do not look upon the protection of the lay public in the same light as others do. Further, some constructive help might be forthcoming for those problems in the subject which are as yet unsolved.

I feel that no one is in a position to discuss the question who has not taken out the complete course of lectures. To the medical man whose time is limited I would recommend the concentrated course which is given in the Great Central Hotel, London, once a month in the winter months. It takes place on a Saturday afternoon and all day on Sunday, and in this time the complete series of eight to ten lectures is given by experts, and the difficult points and problems which have been raised by correspondents in this column have all been answered. In many of these letters there is loose thinking and confusion, owing to the subject not being fully understood, and hence the claims of the Government have been exaggerated.

There are three main types of bombs: the high explosive, the incendiary, and the gas bomb. For the first of these there is no guaranteed treatment—either preventive or therapeutic. Diffusion and scattering of the population, so that concentration of casualties cannot take place, is all that is advised. No claims are made by the Government in this direction at all. For the incendiary bomb, which produces a fire that cannot be extinguished, and can only become harmless by being allowed to burn out, the suggestion is made to form a safe surface of sand or clay to allow this to take place rather than provide a suitable inflammatory material to start the whole house on fire. The suggested treatment may not sound infallible, but it is up to the critics to suggest a better rather than to decry what methods have been suggested, and certainly few in the hour of danger would consider the laying of a layer of sand on the floor of the upper room a task of great difficulty.

For the gas attack the gas mask has been proved a protection for all known non-blistering gases, and the protective clothing for these latter. It is suggested that it is an impossible task to train the "whole" general public—this is admitted—but it is no reason to stop training as many as possible. If a nucleus in every crowd were so instructed the knowledge would be quickly disseminated, and the common sense which they possessed would soon act as leaven in the presence of mass panic, which is one of the greatest dangers of gas attack. The problem of the child, the aged, the delicate and ill (for instance, pneumonia), and the mentally deficient is constantly raised as a reason for not instructing the sane and healthy adults. Surely such a section of the community would not be a street problem in the time of a gas attack.

Another point that is raised, that such instruction is productive of a desire for war, is surely not correct. I would say that a total unpreparedness in this country would make a war from the enemy's point of view a much more attractive proposition. One might as well say that the man who goes out with an umbrella and waterproof is asking for trouble, yet many of us know that this is done frequently by those who claim that it is the surest way to ensure a fine day!

If this subject is to be considered fairly and scientifically it must be divorced from the political bias with which many of the letters so far contributed have been tainted. For this reason I think the suggestion of Dr. Colquhoun, that the subject should be considered by a medical committee, is a good one and worthy of consideration.—I am, etc.,

Belfast, June 28. IAN FRASER.

SIR,—Surely some of your correspondents are missing the main point raised by Dr. Leys. He did not suggest that a doctor should refuse to treat air raid casualties or that the general public or the doctors should refuse to wear gas masks where these are available. His protest was directed against the use of the medical profession as an instrument of Government propaganda in what he considered a deliberate deception of the people of this country. This propaganda is designed to keep up the war spirit of the general population by persuading them that they can be protected against wholesale destruction from the air not only by gas but by high explosive and incendiary bombs. In so far as it is successful this diverts the attention of the public from any effort to enforce the removal of the causes of war and from the general ineptitude of European statesmen, whose only refuge seems to be the madhouse of competitive rearmament. Medical men need make no claim to special knowledge of the causes of international unrest, but they are entitled to refuse to be prostituted for political purposes.

It is surely irrelevant to cite the fertility of Asiatics as an argument against Dr. Frewen Moor's contention that poverty in the modern world is not due to lack of goods. The fact remains that the recent world depression was not due to a lack of the primary consumption goods but to a lack of purchasing power for these goods.—I am, etc.,

Rabley Willow, Herts, July 2. DOUGLAS MCCLEAN.

Incidence of Deafness in England and Wales

SIR,—I was much interested in the article on the above subject by Mr. A. G. Wells, which appears in your issue of July 3, and I note that there is a marked difference in the degree of deafness that is recorded by the audiometer and by tests of hearing of the conversational voice.

We are told, for example, that Grade I covers children who can hear and understand conversational voice at

20 feet or over in ordinary classrooms. If we assume that the ordinary conversational voice can be heard at a maximum of 50 feet, to hear it at 20 feet shows a diminution of hearing power of about six decibels, but we are also told that the hearing loss with the pure tone audiometer is thirty-five decibels in this grade. Now a difference of six decibels means that the sound can be heard at half the normal distance and a difference of thirty-five decibels means that the hearing distance is diminished to about one-fiftieth of the normal. We cannot accept both. We can assume that the diminution is thirty-five decibels, and that the hearing of the patient is 2 feet for the conversational voice and that he lip reads; but we cannot assume that the record for the hearing of the voice is correct, for this would mean that the voice employed could be heard at fifty times twenty —that is, one thousand feet—by the normal ear.

It is probable, however, that this discrepancy arises because the patients were not tested with the audiometer in a specially constructed silent room, in which alone the audiometer records are correct. If the tests are carried out with an audiometer in an environment of even minor degrees of noise, the records given by the instrument are very much too high, and in fact are unreliable for assessment of the degree of deafness from which the patient suffers.

I hate to suggest that there is a discrepancy when Mr. Wells has done so much, but audiometer records and the results of voice tests so frequently show similar discrepancies that it would be very valuable if Mr. Wells could clarify this point.—I am, etc.,

London, W.1, July 5. A. LOWNDES YATES.

Obituary

Dr. HORACE SWORDER died on June 18 at Guildford, where he was living in retirement. Born in 1854, he was educated at Epsom College and at St. Mary's Hospital, London, qualifying M.R.C.S.Eng. and L.S.A. in 1875, and L.R.C.P.Lond. in 1877. After holding the usual resident appointments at St. Mary's he entered into partnership with Dr. Grover at his native town of Luton, continuing there in general practice until he retired in 1924. For thirty years Dr. Sworder served Luton, with great acceptance, as a part-time medical officer of health; his yearly reports were stimulating and progressive, always provoking debate and often opposition. The Luton Children's Hospital is his permanent memorial; it was begun, at his suggestion, in 1889 and formed the chief interest of his life. Childless himself, he was passionately devoted to children, sparing no effort in their service. For sixteen years he acted as medical superintendent of the Children's Home, as it was at first called, and for long years after was the driving force behind the sustained efforts needed to ensure its permanent establishment and success. He conceived and organized a Children's Guild of Kindness with its motto, "Live not for Yourselves Alone," which proved invaluable not only by substantially helping the finances of the institution, but also by establishing a habit of giving and of service among the men and women of the future. In late years Dr. Sworder was a member of the court of the Society of Apothecaries. He was a member of the British Medical Association for sixty years, having been elected in 1877, and he played his full part in all its local activities. In 1898 he was president of the South Midland Branch, and in 1907 chairman of the Bedfordshire and Hertfordshire Division.

Medico-Legal

DAMAGES FOR SHORTENED LIFE

When a person dies as a result of an unlawful act or omission by someone else his representatives may now sue the offender for damages on behalf of the estate. Originally a cause of personal action died with either of the parties to it, but the law was changed by the Law Reform Act, 1934. The change has spread much concern among doctors, whose families may now, as in the case of Connolly *v.* Rubra (*British Medical Journal*, 1936, **2**, 1174; 1937, **1**, 1099) be ordered to pay damages for the negligence of a doctor who has since died. One of the factors which the court takes into account in assessing the damages is the extent to which the expectation of life of the injured person was shortened by the negligence of the offender. The judgement of the House of Lords on appeal in Rose *v.* Ford, which became a leading case as soon as it was tried by Mr. Justice Humphreys in 1935, is therefore directly important to medical men.

The Case of Rose v. Ford

Miss Rose, aged 23, was seriously injured on August 4, 1934, in a road accident for which Mr. B. J. Ford was to blame. On August 6 her right leg was amputated and on August 8 she died from her injury. Her father, Mr. Alfred Rose, as administrator of her estate, claimed damages under the Fatal Accidents Acts, 1846–1908, for the benefit of himself and his wife in respect of the death of his daughter; and also on behalf of his daughter's estate under the Law Reform Act, 1934, to recover such damages as his daughter would have been entitled to at the moment of her death. Mr. Justice Humphreys awarded £300 damages under the Fatal Accidents Acts, and on behalf of the daughter's estate awarded £29 special damages, including funeral expenses, and £500 for pain and suffering and the loss of the leg. He would not award damages for loss of expectation of life, as he considered that the only ground for such damages could be mental suffering caused by the contemplation of early death, and that in the present case no such suffering had been proved.

Mr. Ford appealed against the award of £500 and Mr. Rose cross-appealed asking for damages for loss of expectation of life. The Court of Appeal, on October 28, 1935, reduced the £500 to £22 on the ground that Miss Rose had lived for two days only after the amputation. On the cross-appeal the court agreed that Mr. Justice Humphreys had been wrong in thinking that the ground for damages for loss of expectation of life was mental suffering. Thereafter, however, they disagreed. Lord Justice Slesser and Lord Justice Greene decided that the claim for damages for the shortening of the expectation of life was in substance a claim for the loss of the life and therefore not maintainable under the Law Reform Act, for damages must be calculated without reference to any loss to the estate consequent on the death. Lord Justice Greer disagreed with this decision, holding that the right to such damages vested in the injured person at the moment of injury and survived to the administrator.

Judgement by House of Lords

The House of Lords gave judgement in Mr. Rose's appeal on June 25, 1937. Lord Atkin, the president of the court, referred to the recent case of Flint *v.* Lovell, 1935 K.B. 354, in which the Court of Appeal held that, if a person suffered personal injuries from negligence, the damages could include a sum for the shortening of his normal expectation of life. Mental suffering was not a necessary ground. Shortening of expectation of life had always been a usual element in the assessment of damages for personal injury. He saw a substantial distinction between damages awarded to a living person like Dr. Flint because his life was shortened and damages awarded to a third person because of some other person's death. If a living person could claim damages for loss of expectation of life that right was vested in him in life,

and on his death under the Act of 1934 passed to his personal representatives. Lord Atkin did not see any reason why the fact that the expectation was realized and that death came at the time anticipated or sooner should make any difference. It was not necessary for him to assess the damages, for the Court of Appeal had stated in their judgement that if they were wrong and damages were recoverable, the amount should be £1,000. Lord Atkin therefore expressly left open such questions as whether a rich man's life has greater potentialities of pleasurable enjoyment than a poor man's; or the extent to which physical weaknesses other than those caused by the accident and not affecting the duration of life should be considered; or whether the damages should include a sum for loss of income which the deceased would have received if he had lived a reasonably long time but would not have saved so as to increase his estate. He thought that the award of £1,000 assumed a normal two-legged life, so Mr. Rose could have no more damages for the loss of his daughter's leg. He expressed no opinion whether on another basis of calculation the Court of Appeal would be right in fixing the damages for the loss of the leg for four days only.

It is therefore law that a court may award to the representatives of a deceased person substantial damages for loss of expectation of life, even though the person only lives a few days. The case also illustrates one of the most admirable features of our judicial system, for Mr. Rose, though he sued as a poor person, has been able to appeal successfully to the House of Lords at the expense of the State and of the counsel and solicitors concerned.

The Services

ALEXANDER MEMORIAL PRIZE

Lieut.-Colonel R. F. Bridges, R.A.M.C., has been awarded the Alexander Memorial Prize for the year 1936, consisting of a gold medal and a sum of £40. The prize is awarded annually to an officer of the Royal Army Medical Corps for professional work of outstanding merit.

LEISHMAN MEMORIAL PRIZE

Major A. G. Harsant, O.B.E., R.A.M.C., has been awarded the Leishman Memorial Prize for the year 1936, consisting of a silver medal and a sum of £30. The prize is awarded annually to an officer of the Royal Army Medical Corps, or of the Army Dental Corps, for work of outstanding merit.

NORTH PERSIAN FORCES MEMORIAL MEDAL

R. Lewthwaite, D.M., Colonial Medical Service, has been awarded the North Persian Forces Memorial Medal for the year 1936 for his paper on "The Pathology of Tropical Typhus (rural type) of the Federated Malay States," published in the *Journal of Pathology and Bacteriology*, January, 1936. The medal is awarded annually for the best paper on tropical medicine or hygiene published in any journal during the preceding twelve months by a medical officer, with less than twelve years' service, of the Royal Navy, Royal Army Medical Corps, Royal Air Force, Indian Medical Service, or Colonial Medical Service.

DEATHS IN THE SERVICES

Colonel WILLIAM ALLAN MAY, C.B., late R.A.M.C., died at Bath on May 18, aged 86. He was born at Stoke Damerel on September 18, 1850, was educated at Guy's, and took the L.S.A. in 1873 and the M.R.C.S. in 1874. Entering the Army as surgeon on September 30, 1874, he reached the rank of colonel on March 22, 1903, and retired on September 18, 1907. He served throughout the South African War from 1900 to 1902, when he held the rank temporarily of full colonel while principal medical officer of an infantry division, took part in operations in the Transvaal, the Orange River Colony, and Cape Colony, was present at the actions of Biddulphsberg and Wittebergen, was mentioned in dispatches in the *London Gazette* of April 16, 1901, and received the Queen's medal with three clasps, the King's medal with two clasps, and the C.B. He rejoined for service in the war of 1914–18 immediately it began, from August 6, 1914.

Universities and Colleges

UNIVERSITY OF OXFORD

The following candidates have passed in the examinations indicated:

MATERIA MEDICA AND PHARMACOLOGY.—G. Ashforth, H. M. Balfour, J. T. Burrowes, J. P. Childs, D. H. Davies, R. G. Eager, F. Fulton, A. G. Hardy, S. J. S. Hughes, W. G. J. Hughes, R. M. Lattey, J. A. L. Leeming, E. J. L. Lowbury, D. Micklewright, E. S. Nicholson, F. P. Powell, L. G. C. E. Pugh, R. J. Rossiter, A. J. L. Smith, E. Smith, W. A. H. Stevenson, R. W. Tibbets, R. V. Young, O. C. Sandys.

FORENSIC MEDICINE AND PUBLIC HEALTH.—L. B. Bok, R. C. Browne, S. E. Furber, O. I. Green, R. M. Hugo, E. L. James, J. G. Jamieson, J. B. Longmore, J. E. Lovelock, H. Muller, J. A. Partridge, M. A. Partridge, J. C. Prestwich, R. Roaf, T. R. Savage, N. E. Stidolph, C. M. F. Walters, D. Whitteridge, W. E. Young, R. Billig.

PATHOLOGY.—J. C. G. Abraham, J. M. Almond, J. S. Astbury, J. B. Atkins, D. R. Cargill, D. L. P. de Courcy, C. Exell, L. G. C. E. Pugh, E. B. G. Reeve, J. Scholefield, A. Shannon, E. P. S. Snell, S. F. Taylor, R. R. Wethered, L. L. Whytehead, A. M. L. Isabella, A. C. Kohn-Speyer.

MEDICINE, SURGERY, AND MIDWIFERY.—R. G. Blackledge, W. W. Coppinger, D. I. Crowther, A. C. Grey, G. F. C. Hawkins, M. H. Hughes, D. Jefferiss, J. Mason, R. B. Niven, A. R. Norton, M. A. Partridge, I. F. Rose, A. F. Smith, T. B. Snell, R. H. S. Thompson, B. M. Thornton, C. B. I. Willey, W. Wynne Willson, A. L. Young, W. B. Young, A. J. M. T. Barnes, R. Billig, J. M. Sherring.

M.CH.—M. W. C. Oldfield.

DIPLOMA IN OPHTHALMOLOGY.—C. A. Buchanan, M. M. A. Dubash, V. B. Mankad, J. D. Maude, Y. K. C. Pandit, M. J. Philip, E. V. W. Pockley, L. R. C. Rose, C. A. Stanley.

UNIVERSITY OF CAMBRIDGE

Dr. David Keilin, F.R.S., has been re-elected Quick Professor of Biology. Mr. J. D. Boyd has been appointed university lecturer in anatomy, and Dr. W. A. H. Rushton has been reappointed university lecturer in physiology. Mr. S. J. R. Reynolds and Dr. C. D. P. Jones have been appointed university demonstrators in anatomy, and Mr. A. L. Hodgkin university demonstrator in physiology. Dr. G. N. Myers has been reappointed university demonstrator in pharmacology. All these appointments are for three years from October 1, 1937.

Applications for the Gwynaeth Pretty studentship, the holder of which shall devote himself to original research in the aetiology, pathology, and treatment of disease, with particular but not exclusive reference to diseases which cripple or disable in childhood or early life, should be sent, with copies of papers containing published work and testimonials and references, before August 1, to Professor H. R. Dean, Department of Pathology, from whom further information may be obtained. This studentship, of the annual value of £200, is tenable for three years.

Applications for the Nita King scholarship, the holder of which shall devote himself to original research in the aetiology, pathology, and prevention of fevers, should be sent, with copies of papers containing published work and testimonials and references, before August 1, to Professor Dean. This scholarship is of the annual value of £60.

The Benn W. Levy research studentship in biochemistry will become vacant on October 1. Applications for its tenure should be addressed to Sir F. G. Hopkins, F.R.S., at the School of Biochemistry, before July 24.

At the congregation held on June 19 the following medical degrees were conferred in addition to those reported in this column on June 26:

M.B., B.CHIR.—*E. H. Platts.

M.B.—*M. P. Morel, *S. H. B. Platts, J. W. W. Jepps, M. H. Harding, C. L. Heanley.

* By proxy.

UNIVERSITY OF LONDON

The University Studentship in Physiology for research in physiology, of the value of £100, has been awarded to Juan Pete Quilliam of University College.

Dr. A. A. Miles, F.R.C.P., has been appointed to the University Chair of Bacteriology tenable at the University College Hospital Medical School, and Professor J. H. Dible, F.R.C.P., to the University Chair of Pathology tenable at the British Post-Graduate Medical School, both from October 1.

UNIVERSITY OF BIRMINGHAM

At a congregation held on July 3 the following degrees were conferred:

HON. LL.D.—Sir Gilbert Barling Bt., C.B., C.B.E., F.R.C.S.
M.D. (STATE MEDICINE).—*Ex Officio:* H. P. Newsholme.
M.B., CH.B.—I. Ackerman, Enid I. M. Addenbrooke, *†N. Ameli, †T. E. D. Beavan, R. H. F. Brain, *J. W. Brown, V. H. Cooper, Enid Cyriax, C. M. Fenn, E. R. S. Grice, J. B. W. Hayward, A. C. Houghton, Joanna M. Hughes, Joan J. Lockley, M. Meir, *G. Mitchell, *C. P. Nicholas, W. H. Osborn, H. G. H. Richards, E. J. Richardson, *†Frances B. Robinson, R. L. Sadler, J. H. Sangster, *J. M. Small, O. E. Smith, *† C. W. Taylor, F. H. Vollam, M. A. G. Ward.

* Second-class honours. † Distinction in medicine.

The following scholarships, medals, and prizes have been awarded: *Queen's Scholarship* (third year), J. C. White; (fourth year), P. H. Davison; (fifth year), W. G. Mills; (final year), N. Ameli. *Ingleby Scholarship* (final year), J. M. Small. *Arthur Foxwell Memorial Medal* (final year), T. E. D. Beavan. *Sampson Gamgee Memorial Medal in Surgery* (final year), and *Priestley Smith Prize in Ophthalmology* (final year), R. H. F. Brain. *Russell Memorial Prize,* N. Ameli. *Leith-Newman Prizes in Pathology* (fourth year), Medical, B. A. E. Johns; Dental, S. J. Webb. *Peter Thompson Prize in Anatomy* (third year) and *Bertram Windle Prize in Anatomy,* H. A. Shaw. *John Barritt Melson Gold Medal in Physiology* (third year), J. C. White.

UNIVERSITY OF DURHAM

In convocation on June 29, with the Vice-Chancellor, Sir Robert Bolam, M.D., presiding, the honorary degree of Doctor of Science was conferred on Sir Henry H. Dale, M.D., F.R.S., director of the National Institute for Medical Research, Hampstead; and the honorary degree of Doctor of Surgery on Dr. R. P. Ranken Lyle, emeritus professor of midwifery and gynaecology in the University of Durham.

UNIVERSITY OF ST. ANDREWS

On June 30 the honorary degree of LL.D. was conferred on Angus MacGillivray, M.D., D.Sc., Assessor of the General Council on the University Court, and on William Ogilvy Kermack, D.Sc., of the Laboratory of the Royal College of Physicians of Edinburgh.

UNIVERSITY OF GLASGOW

The King, on the recommendation of the Secretary of State for Scotland, has approved the appointment of Noah Morris, M.D., D.Sc., F.R.F.P.S.G., to be Regius Professor of Materia Medica in the University, in the place of Professor Ralph Stockman, resigned.

UNIVERSITY OF WALES

The following candidates have been approved at the examination indicated:

M.D.—Ll. M. Edwards, Dorothy M. James.

The following candidates have satisfied the examiners in the examination indicated:

DIPLOMA IN PUBLIC HEALTH.—(*Part I*): R. M. Dykes, W. J. M. Evans, D. T. Richards, B. A. Thomas, D. A. O. Wilson.

NATIONAL UNIVERSITY OF IRELAND

UNIVERSITY COLLEGE, CORK

The following candidates have been approved at the examinations indicated:

M.B., B.CH., B.A.O.—*J. N. Twohig, *J. Burke, †J. F. J. Hickey, †M. Lentin, †R. G. G. Barry, †J. J Martin, J. Galvin, H. Gremson, J. P. Lane, Margaret M. Loughnan, J. J. McCarthy, D. F. Murphy, T. K. Murphy, P. L. O'Neill, T. Sheahan. *Part I:* Ellen M. M. Murphy. *Part II and Pathology:* C. Marchment, P. J. Ryan. *Part II:* P. O'Flynn. *Pathology:* D. O'Keeffe.
D.P.H.—M. J. McCarthy, J. O'Herlihy.

* First-class honours. † Second-class honours.

SOCIETY OF APOTHECARIES OF LONDON

The following candidates have passed in the subjects indicated:

SURGERY.—W. D. Brinton, O. D. Gilmore, F. H. Holder, R. Robins-Browne.
MEDICINE.—J. R. Audy, G. R. Hopper, R. Robins-Browne.
FORENSIC MEDICINE.—J. R. Audy, R. Robins-Browne.
MIDWIFERY.—J. B. Alexander, B. M. Hulse, L. De C. Kite, H. A. N. Passmore, G. G. Sahasrabuddhe.

The diploma of the Society has been granted to J. R. Audy, G. R. Hopper, R. Robins-Browne, and G. G. Sahasrabuddhe.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

Election to the Council

Three Fellows were elected on July 1 into the Council to fill the vacancies caused by the retirement in rotation of Sir Holburt Waring, Bt., Mr. C. H. Fagge, and Mr. W. Sampson Handley. The result of the poll was as follows:

	Votes
WILLIAM SAMPSON HANDLEY (Middlesex) ...	665
CHARLES HERBERT FAGGE (Guy's)	605
CECIL PEMBREY GREY WAKELEY (King's College)	480
James Ernest Helme Roberts (St. Bartholomew's)	367
Vincent Zachary Cope (St. Mary's)	359
Sir Lancelot Edward Barrington-Ward (Great Ormond Street)	287
William Hugh Cowie Romanis (St. Thomas's)	248
Walter Goldie Howarth (St. Thomas's) ...	217

In all 1,227 Fellows voted; in addition thirteen votes were found to be invalid. Mr. Fagge, Mr. Handley, and Mr. Wakeley are all elected for the full period of eight years.

Medical Notes in Parliament

The Royal Assent was given on July 1 to the Children and Young Persons (Scotland) Act, the Widows', Orphans', and Old Age Contributory Pensions Act, the Public Health (Drainage of Trade Premises) Act, and other Acts, and on July 6 to the Exportation of Horses Act, the Road Traffic Act, and the Hydrogen Cyanide (Fumigation) Act.

The Hairdressers (Registration) Bill, introduced by Lord Strabolgi, was read a first time in the House of Lords on July 2. On July 6 the Physical Training and Recreation Bill passed through committee of the House without amendment, and the Cinematograph Films (Animals) Bill and the Teachers (Superannuation) Bill were read a second time.

The Vote for the Ministry of Labour, the Finance Bill, and the Agriculture Bill have been the chief business of the House of Commons this week. The Cinematograph Films (Animals) Bill was read a third time by the House on June 29.

Sir Frank Fox, secretary of the Empire Rheumatism Council, and Dr. W. S. Copeman addressed the Parliamentary Medical Committee at the House of Commons on July 1. They explained that the Empire Research Council was being established on the lines of the British Empire Cancer Campaign, and as a result of a report by a special committee of the Royal College of Physicians. At the same meeting Dr. Davies, professor of pathology in the University of Hong Kong, spoke about a report made by a committee to the Hong Kong Government, which suggested a general curtailment of the university and, in particular, of the medical faculty and its research work. Sir Francis Fremantle, who presided at this meeting of the Parliamentary Medical Committee, and Mr. K. W. M. Pickthorn, who was invited to attend as a member for Cambridge University, went after the meeting to put the facts about Hong Kong before Mr. Ormsby Gore, who arranged for the matter to be brought before the Education Advisory Committee at the Colonial Office.

The Local Government Superannuation Bill was read a third time in the House of Commons on July 2, after a discussion about its application to officials whose military service during the war was voluntarily extended after November 11, 1918.

On July 2 also the Trade Marks (Amendment) Bill passed through report and third reading. Allusion was

made to the use of such trade names as "aspirin," "aspro," and "yeast-vite."

On July 5 the Hydrogen Cyanide (Fumigation) Bill passed through committee of the House, and the Agriculture Bill was read a second time.

The report by the Government Actuary on the Fourth Valuation of the Assets and Liabilities of Approved Societies was laid on the table of the House of Commons on July 5.

Health Services of Scotland

Dr. WALTER ELLIOT, in the House of Commons on June 24, brought forward the estimates for the Department of Health for Scotland, including a grant-in-aid of the Highlands and Islands Medical Service and grants under the National Health Insurance Acts. He said no one in Scotland was completely satisfied with the position in that country. Improvements would have to be made in the health services and in housing. There was no reason for despondency but every reason for action. Since the estimates were last considered a report had been received on public health services from an inquiry carried out under the chairmanship of Professor Cathcart. There had also been an inquiry carried out by the Department itself into the working of the block-grant system. This had been followed by legislation which improved the central grants to Scottish local authorities to the extent of nearly £1,500,000 a year. The Maternity Services Act had recently passed through Parliament, a vote for physical training had been carried, and a Bill had just been presented to close the gap between leaving school and entrance into health insurance. Infant mortality last year was 82 per 1,000 births. That was higher than the rates for the previous three years, but lower than the rates before 1933. The rate over the whole country for the first quarter of 1937 showed a marked improvement over that for the similar period of 1936, while the rate for sixteen large Scottish towns over five months of 1937 showed that the improvement had continued. Notified cases of influenza in Scotland rose from 43,000 in 1935-6 to 123,000 in 1936-7. Cases of whooping-cough—a serious malady last year in Scotland—rose from 1,144 in the first quarter of 1936 to 8,417 in the first quarter of 1937. In spite of these epidemics the health of Scotland continued to improve taken generally.

The Department was taking action on some of the lines recommended by the Committee on Scottish Health Services, and action would have to be taken on many more. The committee dealt with the need of a new sanitary code and the organization of hospital services. That work was proceeding. It dealt also with the need for extended general practitioner service, and recommended medical benefit for the dependants of insured persons. The most important of the committee's recommendations referred to maternity and child welfare. The Government had passed the Maternity Services (Scotland) Act, 1937, which came into force on May 16. There was no case under the Act in which a certified midwife would not be present during the whole time of labour, and in addition a medical man would be notified and would hold himself in readiness to attend. The maternity figures for Scotland had come down this year, and maternal mortality was at present the lowest recorded in Scotland; there was a saving of some sixty lives over the figure for the previous year.

SLOW HOSPITAL REORGANIZATION

Reorganization of hospitals under local authorities was not proceeding as quickly as they would wish. Some of the bigger authorities had taken steps for comprehensive schemes under the Act of 1929 and many were taking steps of their own to bring their hospital service up to date. A scheme which would give Lanarkshire as a whole a new general and a new maternity hospital as well as improved care of infectious diseases would have been well on its way, but unfortunately the large boroughs would not combine with the county council. Further provisions were being examined by the county council and two of the boroughs, three of the boroughs having decided to stay out. Provision was being made for a new municipal hospital at Greenock for the care of the general sick. Unfortunately Port Glasgow decided not to participate in the scheme on the ground that it would not have a share in the management of the institution. In Dumfries and Galloway arrangements were going more smoothly. There the local authorities were in negotiation with the voluntary hospitals as well, which was very desirable. In the north some six local authorities had jointly agreed to maintain a consulting physician at the Northern Infirmary, Inverness. Four schemes adopted under Section 27 of the Local Government Act, 1929, covered 800,000 of the people of Scotland, the authorities in question being Edinburgh, Dundee, Aberdeen Borough, and Bute. It seemed odd that the desirability of a general scheme of this kind should so far have appealed only to six authorities.

In the Highlands and Islands the schemes under discussion were extensions of hospitals at Lerwick, Kirkwall, and Stornoway. At Lerwick, with Treasury approval, the Department of Health had promised the managers of the Gilbert Bain Hospital a grant of 80 per cent. of £45,000, the estimated cost of a new hospital. In Kirkwall the Balfour Hospital trustees had applied for a grant to enable them to extend the hospital at a cost of £10,000, and the application was receiving sympathetic consideration. At Stornoway the managers of the Lewis Hospital had been promised a grant of £14,000 from the Highlands and Islands Medical Fund for extension of the hospital.

HEALTH OF SCHOOL CHILDREN

So far as school children were concerned the big constructive measure in addition to medical inspection was the milk-in-schools scheme. In certain areas the increase in numbers under the scheme had not been what was wished. In Lanarkshire, in the spring of 1936, 67,000 children were having milk in the schools, but since then the figure had dropped to 35,000. He did not know the reason for such a decline, which showed itself in areas where a great quantity of the milk was supplied free as well as in areas where half-price was charged. This was not satisfactory and required further consideration. Nevertheless in Scotland 294,000 school children were getting a ration of milk every school day. This would manifest itself in improved health, particularly in the condition of the teeth. The condition of the teeth of the people of Scotland was bad and that of the school children was unsatisfactory, and a supply of mineral salts must show itself in improved dentition and ultimately save expense to the local authority or to the individual. Since this subject was last before the House Berwickshire, Roxburghshire, and Selkirkshire had been brought within the ambit of the scheme. Further surveys were being undertaken by Professor Cathcart and Sir John Orr, and the northern survey under Sir John Orr was being supplemented by assistance from the Carnegie Trust. The fullest co-operation was afforded by the Education Department and the Departments of Health and Agriculture. It was worth remembering how far Scotland had advanced in the health of school children. As recently as in 1901 the mortality of children between 5 and 14 was 3,700 deaths. Last year the figure was about 1,500. In 1870 6,000 children between 5 and 14 died in Scotland, although 40 per cent. of the population was then rural as against 20 per cent. at present, showing that fresh air was not sufficient to produce health.

Turning to the question of water supplies, Dr. Elliot said regional schemes were in progress in the rural areas of Dumfries and Kirkcudbright, and similar schemes were under consideration by other county councils. He hoped an increase in money available under the block-grant would form a source from which these desirable reforms could be accelerated. Assistance had been given by the Commissioner for the Special Areas to water supply schemes totalling £225,000, and the Committee on Scottish Health Services recommended a special grant for water supply in the Highlands and Islands, where there was a special problem. In the past seventeen years they had built in Scotland about 250,000 houses, which meant that nearly one million people had obtained better accommodation, but another 250,000 houses were required, and they could not take another seventeen years to build

them. There were 100,000 houses in Edinburgh, and they had to build a new city of Edinburgh every four years. At present they were only building at the rate of a new city of Edinburgh every eight years. Local authorities were doing their utmost to apply the principles of town planning to the new areas which were being built—in some cases not satisfactorily.

REDUCTION MOVED

Mr. TOM JOHNSTON, moving a reduction of the Vote, said that the annual report stated that infantile mortality was 30 per cent. worse in Scotland than in England and Wales. They also know that in the chief infectious diseases Scotland was two and a half times worse than England and Wales. On the other hand, the health conditions of school children were improving, although the evidence of the county of Angus, which included the city of Dundee, showed that in secondary schools boys were 2 inches taller and 5 pounds heavier in weight at the age of 12 than were boys in the burgh schools. Similar figures had previously been supplied by the medical officer of health for Glasgow and by medical officers of health in other parts of the country. Under the scheme for supplying milk to schools every child between 5 and 14 years during school life received milk at 1s. per gallon, but in the case of the child of 4 who was not at school 2s. a gallon was charged for the milk. How could that be justified? Milk was delivered in bulk to institutions at 1s. 2d. a gallon and only 4d. to 6½d. a gallon was charged to the manufacturers. It had been said that disease cost us three hundred million pounds a year. It would pay to supply milk at 1s. a gallon to the mothers and babies instead of handing it over at 6d. a gallon for the purpose of chocolate manufacturers. If Dr. Elliot took up this question he would have the active sympathy of both the Scottish and English Milk Boards. If the price of milk was reduced to 1s. a gallon it would increase by 3s. 9d. a week the purchasing power of the average family of five units.

HIGHLANDS AND ISLANDS: INADEQUATE HOSPITAL ACCOMMODATION

Sir ARCHIBALD SINCLAIR expressed his appreciation of the prominence Dr. Elliot had given to the hospital services that day for the first time in debates on the Scottish Health Department. Progress in those services was slow, and he hoped the Secretary of State would press it on. He was delighted to hear that a consulting physician had been appointed to the hospital at Inverness and was sure his services would benefit the Highlands. The Department of Health in its report for 1936 quoted a section of the report of the Committee on Scottish Health Services which acclaimed the Highlands and Islands Medical Service as an outstanding success. The Medical Service Committee, however, had made a recommendation for the improvement of the service. They said additional hospital accommodation and specialist services for medical and maternity patients should be provided, and also additional nurses and a further equipment of nurses with motor cars. He would like to know whether these recommendations were being pursued. He did not see anything in the Health Department's report about extended provision for refresher courses for nurses and little about the improvement of nurses' housing conditions. An additional grant-in-aid of the local authorities' health services in the Highlands and Islands was an urgent matter.

Mr. WELSH said the number of rural houses in Lanarkshire was 57,675. Of these, in the year 1936, only 1,177 were inspected, and of those inspected 46 per cent. were found to be unfit for habitation. Of the 57,675 rural houses 22,252 were overcrowded by the Department's own standard. At the end of 1936 not a single house was being built in the rural areas of Lanarkshire for the purpose of dealing with overcrowding.

Mr. KIRKWOOD said he had just come back from a cruise round the Western Isles and had never seen healthier and happier children, largely owing to the medical services that have been instituted in the Highlands and Islands. The doctor at Stornoway had drawn his attention to the fact that the hospital accommodation was inadequate. The doctor told him that at the sanatorium in Lewis they could not get fresh eggs, although there was no reason why they should not be supplied.

Mr. LEONARD said the dental condition of school children according to the Department's report was one of the major problems of the school health services, yet only fifty-one full-time and thirty-one part-time dentists were engaged. That meant only one person attending to 12,000 children, although there should be one qualified dentist to every 5,000 children. There were only fifty nursery schools in Scotland attended by 1,800 children, and of that number thirty-six were run by voluntary bodies. The death rate from pulmonary tuberculosis was the lowest on record—55 per 10,000—but the death rate from the disease was the same as last year—74 per 100,000. Had anything been done by the Department to bring to the notice of the competent authorities the special report on the need for greater co-operation and the general advancement in the treatment of tuberculosis?

Mr. WEDDERBURN replied for the Government, and said the Department of Health had drawn the attention of local authorities to the need for providing the fullest supplies of milk in maternity and child welfare centres. The Department would probably issue another memorandum dealing comprehensively with this point. Administrative action on milk prices that could be taken through the agency of the Milk Marketing Board would have to be discussed on the vote for the Department of Agriculture. Mr. Kirkwood would be glad to know that the hospital at Stornaway would not be delayed through the pressure of other building works.

On a division the motion for reduction of the Vote was defeated by 118 to 84.

Trade Effluents

The Public Health (Drainage of Trade Premises) Bill was considered on report in the House of Commons on June 23 and was read a third time. On the third reading Admiral BEAMISH said the Bill was capable of reducing the pollution of rivers, but he asked whether the laws which existed apart from this Bill could and would be enforced. At present the Rivers Pollution Prevention Acts were not put into force. They were full of legal loopholes, and there was overlapping responsibility on almost every river in the country. Authorities concerned with the enforcement of the anti-pollution laws were often pollutors of the streams themselves. Sir KINGSLEY WOOD said he would endeavour to see that the Bill was put into operation properly, and he relied on the co-operation of the local authorities. The Bill had received general approval.

Marriage Bill

The Marriage Bill, which has already passed the House of Commons, was before the House of Lords on June 24 when Lord ELTISLEY moved its second reading and explained its provisions. He said divorce would be permitted where the spouse was of incurably unsound mind. Such persons must have been continuously under medical care and treatment for not less than five years immediately preceding the presentation of the petition and must have been found by the court to be incurably insane. With these safeguards there could not be legitimate ground for alarm. Clause 6 prescribed new grounds on which a marriage could be set aside by reason of nullity. All these grounds had been recommended by the majority of the Royal Commission of 1912. One ground was that either party at the date of the marriage was of unsound mind or epileptic, and another that the respondent was suffering from venereal disease. If proceedings were instituted under these headings the petitioner must have been ignorant of the facts at the time of the marriage.

Lord FITZALAN OF DERWENT opposed the Bill.

The ARCHBISHOP OF CANTERBURY said he could not support the inclusion among grounds for divorce of insanity as defined in the Bill, and he believed the proposal marked a retrograde step in medical science, which increasingly regarded this disease as one capable of cure. He was prepared to support the nullity grounds for divorce.

Lord SNELL referred to the position of the man with children whose wife had become mentally sick and for whom there was no relief, and he appealed to the House to give the Bill an uncontested second reading.

Lord ATKIN said the clause about nullity was unusual in providing that the spouses might have their marriage annulled if there had been recurrent attacks of epilepsy, or if one of the spouses was suffering from venereal disease. There was no definition of the latter. It did not mean communicable venereal disease because that would be cruelty which would be enough to secure divorce. The causes he had mentioned, which were entirely new, might not be discovered within twelve months.

The BISHOP OF DURHAM said that when he looked at the conditions under which insanity was to be declared a ground for divorce, and when he consulted medical authorities, he found the probability of the insanity being cured was so slight that it really would be irrational to make that a basis for refusing relief which might fairly be claimed by a large number of people.

Lord ALNESS said the majority report of the Royal Commission on Divorce was entirely in favour of making insanity a ground for divorce. It pointed out that insanity differed from most other maladies in that in involved a complete break-up of the household and removal of the patient perhaps for years. If it were said that insanity was due to misfortune rather than to fault, he had yet to learn that decrees of divorce were handed out as a reward or a punishment.

On June 28 the debate was resumed by the BISHOP OF BIRMINGHAM, who said he was in favour of the provision that insanity, on the conditions laid down, should be a ground of divorce.

The MARQUESS OF SALISBURY opposed the Bill, and asked why, if they were to include as a ground for divorce insanity because it made marital relations impossible, they should not include every other disease that made marital relations impossible. Who was to say when insanity was incurable? It could only be a matter of opinion of one or more doctors. Persons suffering from melancholia would have cruelly added to the weight and burden of their fears the anxiety that their melancholia might become incurable, that divorce would then be hanging over them, and that they might be deserted in a time of great need.

LORD DAWSON OF PENN'S VIEWS.

VISCOUNT DAWSON OF PENN said that collusion, adultery, and perjury, injuring as they did the characters of the people who resorted thereto, and having the further objection of damaging respect for the law in the eyes of the public, were very great evils. Some of the speakers were disposed to say that collusion and adultery were due to a weakening of the fabric of the moral sense. One speaker had even referred to licentiousness as being the cause. Were not the causes of our present troubles to be found in the changes in thought and in mind which had taken place in the course of the years? Changes must come, whether they were in thought or conduct, and what was to him so difficult to understand was why the idea of marriage should alone be expected to remain static. Where the kernel of marriage had been lost, the tendency of the present age was to throw away the husk—and could we say that it was wrong? The law, having lost its social sanction, was increasingly disregarded. Surely the cure was to adapt the law to the prevailing mind of the community, and this was what this Bill seemed to do.

The increase in divorce did not mean a corresponding increase in marriage failures, because in former days more married people lived with their failures. To-day these failures were jettisoned when they were so irremediable as to make family life a pretence and a damage to the children. Further, in the past the wife had no more equality in sex than she had under the law. Often she was but the passive recipient of her husband's sex needs, while her own sex life was too often submerged by repeated and alternating periods of pregnancy and lactation. In the years preceding the war freedom and equality were coming to women, and with this an increase in sex-consciousness. The war accentuated these changes, and henceforward men and women had a freedom of companionship hitherto unknown. The result of women being more sex-conscious was that a woman expected a sex-satisfied life, just as she demanded equality of companionship, and if deprived of this discontent and a sense of failure were apt to follow. It followed, therefore, that women did contribute more to marriage failures than they did in days gone by, when woman was a more submissive partner. On the other hand, it was his belief that marriages which were successful to-day reached a higher level of happiness than at any previous period.

Passing to the clauses of the Bill, Lord Dawson said that the object of the five-year clause, as he understood it, was to prevent the break-up of marriage for a cause which was transient and curable. He suggested that five years was too long. New attachments would be very apt to arise during the waiting period, and he had his doubts whether they would stand the test of five years' celibacy. That was a reasonable term, perhaps, for someone in their early twenties, but it became a much more serious matter if a woman of 28 was asked to wait five years. It would carry with it the grave disadvantage that it would be destructive of the possibility of a second marriage. He regretted that the Bill did not attempt to deal with or devise means of disentangling and remedying the causes of marriage disharmony in their early stages. Members of his own profession knew full well how many were the misfits of marriage. The trouble might be physical, it might be psychological, which come to them in the guise of ailing health, and how often by imparting knowledge and understanding an endangered marriage might be put straight. Ways and means for making such help widely available would be well worthy of exploration.

INSANITY AS GROUNDS FOR DIVORCE

Lord Salisbury had touched on the subject of insanity, and had said it was impossible to depend on the opinion of doctors. Lord Dawson's answer was that in this imperfect world we had in all our daily relations to trust to those who were expert in the varied branches of knowledge and experience. The care with which matters of insanity were considered by his profession, checked and controlled as they were by their colleagues of the law, gave greater security to the sufferers from mental disorders than was given in any other country in the world. When we came to insanity, he agreed that we were up against difficulties. If we limited the period of continuous treatment to three years he thought we might exclude the chances—and the reasonable chances—of recovery. There was this further reason against making the period too short—that the patient might have a knowledge that he or she was in danger of divorce, and, in some instances, anxiety as to a possible divorce might prejudice the patient's recovery. He had a suggestion to make which he thought was a substantial one. It should be either a continuous period of five years or—and he regarded this as very important—whenever a recurrent form of mental disease had been established. If we increased the period and paid special attention to the feature of recurrency we should provide a just solution for both the patient and the patient's home. There were certain forms of insanity which were cyclical.

There was one important omission from the Bill—homosexuality should be made a cause for divorce alike for men and women. He regretted also the omission of inveterate alcoholism and inveterate drug-taking. Only members of his profession knew the desperate state of fear in homes when one of the partners was the victim of inveterate and incurable drug addiction or alcoholism. Drug addiction, though more subtle than alcoholism, could bring destruction to families with an ease which we all wished to avoid. He supported the second reading of the Bill. With certain amendments it would make, in his judgement, more firm the institution of marriage, and make life more honest, more just, more in accordance with the facts of life.

Lord MAUGHAN said that there was an elaborate insanity definition in Clause 3. The number of persons who recovered

after five years' continuous treatment in one of the places mentioned in the clause was very small. In the committee of the House of Commons it was stated to be 1 per cent., but he thought that was a mistake. It should be put a little bit higher. But assuming that 2 per cent. recovered after five years in a place of detention, the question they had to ask was this: "How many of these 2 per cent. are persons of whom the doctors in charge of the institution would declare on oath that they had shown no signs of improvement during the five years?" He did not think that the two conditions could possibly be fulfilled so as to leave open cases where there would be future recovery. The number of those who would recover after five years being as small as it was, and the fact that if there was ever going to be an improvement it would be observable during the five years, their Lordships might be satisfied that not one case in a thousand would slip through the two-fold qualification necessary to fit the case as one within the Bill, if the Bill passed in its present form.

The Bill was read a second time without a division.

Delusional Insanity in Dartmoor Prisoner

Mr. D. N. PRITT asked on June 24 whether the system called "knock" whereby prisoners under punishment were awakened by a warder knocking on their cell door at short intervals throughout the night was, or had recently been, in operation at Dartmoor; whether it had official sanction and, if so, in what circumstances. Sir SAMUEL HOARE replied that there was no foundation whatever for the suggestion that such a system existed, or had recently existed, at Dartmoor or any other prison.

Mr. PRITT also asked if the attention of Sir Samuel Hoare had been drawn to the case of a prisoner at Dartmoor who had a crippled arm and was certified insane and removed to Broadmoor; whether that prisoner was still at Broadmoor; whether he was now sane, and, if not, from what form of insanity he was suffering; whether his insanity was brought about wholly or partly by his treatment in Dartmoor; whether his arm became crippled as a result of an attack upon him by a prison officer at Dartmoor; and whether any inquiry had been, or would be, held into the circumstances under which his arm was crippled. Sir SAMUEL HOARE presumed that the case referred to was that of a prisoner who in April of last year sustained a deep cut on his right forearm from broken glass. The circumstances were fully investigated at the time by the Board of Visitors, whose inquiry showed that there was no foundation for the suggestion that he had been attacked by a prison officer. The suggestion that the prisoner subsequently became insane owing to his treatment in prison was equally unfounded. His mental condition had improved but he was still unfit to leave Broadmoor Asylum. He was suffering from delusional insanity.

Death following Diphtheria Prophylaxis

On June 24 Mr. LEACH asked the Minister of Health whether he was aware that an Irish jury attributed a death from generalized tuberculous infection following prophylactic inoculation against diphtheria to the presence of tubercle germs in a bottle of prophylactic supplied by the English firm of chemists who supply most of the diphtheria prophylactic used by public authorities in England and Wales; and whether he would have a searching inquiry made into this matter in view of the seriousness of the allegation made.

Mr. BERNAYS: I have seen a Press report to the effect stated in the first part of the question. As to the second part, careful inquiry concerning the prophylactic supplied by the firm referred to has already been made by medical officers of my Department, and the result leads to the conclusion that no tubercle bacilli were present. As the matter is somewhat technical I will send the hon. member further particulars.

Medical Supplies to Bilbao

On June 28 Miss WILKINSON asked the Secretary of State for Foreign Affairs whether it was upon instructions from the Foreign Office that medical supplies were not allowed to be sent back in the *Habana* on its return to Bilbao, although the invoices showing that the boxes only contained medical supplies were shown to the Foreign Office.

Mr. EDEN: The Foreign Office was approached by the Spanish Medical Aid shortly before the *Habana* was due to return to Spain from this country at the end of last month with a request for permission to place medical supplies on board. In view of the clear assurances given to the insurgent authorities that Spanish refugee ships receiving the protection of His Majesty's ships should return to Spain in ballast, it was decided that to agree to this request might prejudice future evacuation arrangements. At the same time His Majesty's Government offered to provide information regarding sailings to Bilbao of British merchant ships which might be willing to carry medical supplies.

Physical Training and Recreation Bill

The Physical Training and Recreation Bill (the provisions of which were summarized in the *Supplement* of April 3, p. 166) received a second reading in the House of Lords on June 29. Earl STANHOPE, who moved the second reading, said that the demand for increased opportunities for physical training and fitness, particularly among the younger generation, was one of the most striking phenomena of the present day. He based the demand for physical training and fitness on the results of national education. For many years they had been improving physical training, and whereas only some two hours a week used to be given for playground exercises and gymnastic activities, at present it was not uncommon in elementary schools for a period of physical activity to be provided for every day. Since the war they had been pressing for a wider and more varied syllabus of physical training to include an adequate daily period of exercise, organized games, swimming instruction, and gymnastics. The result had been that children had left school with a desire for physical exercise, which had been passed on to many of their elders. When the House of Lords debated the question of national physique last November, Lord Dawson of Penn remarked that they ought to distinguish between physical education and physical recreation. He (Lord Stanhope) wanted both. He wanted the physical education given in schools compulsorily, and in such a way that it would become a hobby and a physical recreation to children when they left school and in their later years. It was to provide facilities for physical development after leaving school that the Government had produced this Bill.

The scheme was entirely voluntary. It was based on existing organizations. The object was to mobilize voluntary effort and to join it with the extremely valuable work already being done by local authorities. The tradition of the best voluntary organizations was not that the training should be purely physical. They had also aimed at training minds, and their objective had been a healthy mind in a healthy body. That fitted in with the aim which had been constantly before the Board of Education for many years—that a child should be made fit mentally, physically, and socially for the life which lay before it. The scheme was in no sense military.

Although there was no mention of a drill hall in the Bill there was mention of gymnasia. In this country, being so largely urbanized, it was very difficult to provide open spaces where games could readily be played, and it was difficult for those who worked in great cities to find the time to get away when their work was over to play games except at the week-ends. Therefore a good deal of physical training had to be done in gymnasia. Particularly was that true during the winter months. In foreign countries they had always started with gymnasia and gymnastic clubs, and it was only comparatively recently that they had taken to games and outdoor sports. We in this country started at the other end, and it was only recently that we had realized the value of gymnastic training. While it was possible to become very fit by gymnastic training alone, or even by home training, this was extremely dull, and a national system which confined itself solely to gymnastic training and physical jerks would never be a success. Therefore gymnastic training would be joined with outdoor sports and outdoor games.

The Bill filled a very widely felt want. The knowledge of the value of physical training and physical culture was growing very rapidly throughout the country, and people needed greater facilities than they had at present. Even now that knowledge was nothing like so widespread as it should be. A very large number of people, including those who sometimes were responsible for the better-known public schools of the country, had not yet realized the value of physical training. A good deal had yet to be done to make its value more widely known, and power was taken in Clause 3 for the Board of Education, in consultation with the National Advisory Council and with the recommendation of the Grants Committee, to spend money on publicity and propaganda.

ADEQUATE NUTRITION BEFORE PHYSICAL TRAINING

Lord STRABOLGI welcomed the Bill. He said there ought to be a separate Ministry for the whole range of sport and physical culture, and everything in connexion with that side of human activities. With more and more people living in great cities something of that kind was absolutely necessary. They could spend money upon and organize, encourage, and stimulate physical culture, physical exercises, and recreation as much as they liked, but if they had a large section of the people undernourished or suffering from malnutrition all that would be wasted. Wholesome and sufficient food was more important for many of the poor people to-day than physical jerks. At present a large section of the population did not get sufficient food of the right quality to keep them in proper health.

Viscount BLEDISLOE said that on returning after five years' residence in New Zealand he was shocked at the relative neglect of national physique in this country. As president of the National Council of Social Service he welcomed the Bill because it definitely combined Government action with the work of voluntary organizations. He had had the opportunity, during the last two years, of seeing some admirable work of voluntary associations in every sphere of social activity, including physical training and welfare, in different parts of the country, and notably in the Special or Distressed Areas.

Lord ABERDARE said that the ideal behind this campaign was that of personal fitness: fitness for the greater enjoyment of life. He agreed with the whole structure of the Bill. He foresaw as a result of it a great strengthening of the moral fibre and character of the citizens of the country. That, among other things, should go a long way to reduce the number of inmates of the prisons and asylums. He foresaw better health, which would mean less medicine and drugs, and should go far to relieve the pressure on the hospitals. He foresaw better mental balance and alertness, which should have very far-reaching effects, even so far perhaps as to reduce the number of deaths on the roads. He (Lord Aberdare) would like to see all exercise taken in the fresh air, but with our climate gymnasia were generally a necessity. The Council on Physical Training was also concerned to provide for swimming, walking, cycling, and all forms of sport and exercise.

FUNCTIONS OF THE NATIONAL COLLEGE

The Government was taking steps to improve nutrition, which meant better housing and better working conditions as well as supplying extra food in certain cases. This country was one of the best fed in the world. No school child need be underfed, and ample powers and machinery existed for feeding children who needed it. The machinery could be used, and the responsibility lay largely with the teacher, who had emergency powers to put a child on the food or milk list until a doctor could be seen. No one would purposely put children through a course of physical training which would be too much for them, but this subject had been over-stressed and did not really arise under the Bill. A recent routine examination in London schools showed that of 184,733 children examined - these were unselected children—only 122 were found to be seriously ill-nourished, and only 1,500 seriously under-nourished. Recently he was told by a reliable social service worker that he saw no sign of under-nourishment in Battersea.

At the National College there must be an adequate supply of teachers, leaders, and organizers. It was necessary to see that facilities throughout the country were properly used, and to keep people enthusiastic. The National College was a vital necessity, not only for this purpose but for carrying out the essential medical research. Perhaps the College was the mainspring of the whole movement. The Council must arouse a personal ambition in everyone to be fit and healthy. For this purpose they would need to use all the resources of modern publicity, such as posters, booklets, and films. They must keep physical training and recreation steadily before the people and encourage them to use their leisure hours wisely.

LORD DAWSON AND A CREATIVE POLICY

Viscount DAWSON OF PENN said he agreed with Lord Aberdare that this Bill was of vast importance, because it gave method and structure to a policy which would aim at the promotion of the fitness of the nation. It was not only necessary in the interests of the present generation but of future generations that they should be given the best opportunity to turn those great potentialities which are particularly notable in the British race into actualities. We had only to go back to the time of the war to visualize what powers were in our blood. His belief was that if the youth of the nation got the opportunity of a training in fitness they would create a surprise by the rapid way in which they would respond, for they had a certain elasticity, not only of body but of mind, which made them respond very easily to advantages in the way of physical education.

Not only was this an important matter to the present generation, but a higher standard of physical fitness was necessary for the preservation of the nation in future generations. In securing a fit race in days gone by Nature did a large part of the work. She killed off the unfit, and only the fit survived. We were gradually undoing Nature's efforts by our developed sense of greater humanity and a more acute conscience towards those who were in distress and those who were weak. If we were to continue that policy of looking after the weaker brethren—he could not conceive anybody doubting that that was a right policy—we must remember that we were at the same time undoing Nature's plan for discarding the weaklings. It therefore became doubly important for us to set up a policy which would create fitness. If we created fitness and gave the proper opportunities it was inevitable that the more fit and efficient would come to the fore. Consequently, the more fit and efficient would lead the nation. The young were all hero worshippers, and would follow the leaders of their own generation. If, therefore, the opportunity was given to those who were most fit to move forward, as they inevitably would, in the company of their generation, they would set the pace of conduct and the standard of fitness for those who came after them.

He agreed with Lord Aberdare that from one point of view the National College was the pivot of this scheme. If we had a suitable college—he hoped it would be within reach of London—and if that college was erected in suitable and large enough grounds, we should be able to have a community of students, where they would learn the technique of their business, where men and women who were going to take up physical education as a whole-time job would be trained, and, in addition, where organizers and leaders for the voluntary organizations could receive a training of lesser duration and less strenuousness. He hoped also that we should be able to choose the best of the boys who were passing into adolescence and give them at this college a special six months' training, so that we might test out those who were potentially fit and be able to give those who turned out to be fit the opportunity of becoming the leaders of their generation in the walks of life which they individually pursued.

INSTRUCTION IN CHOOSING AND COOKING FOOD

On the subject of nutrition Lord Dawson said the distribution in this country of what was called malnutrition, but was, he thought, very often more accurately called undernutrition, was patchy. If one went to the London elementary schools one was very much impressed with the great change

in the children. They were for the most part well nourished, even in the poorer districts; they were well dressed; they were a different generation from the children we used to see years ago. On the other hand, if one went to the distressed areas, where unemployment was rampant, he agreed that there were places where under-nourishment might be found, and in some places one could not get away from it; it was quite obvious. In connexion with under-nutrition we were apt to lose sight of the fact that so many of the people of this country who were the heads of households had never been taught how to choose food. They did not know how to spend their weekly earnings to good advantage. Further than that, so few of them know how to cook the food. If one compared this country with certain countries on the Continent the difference was manifest. If one went into the homes here one might see children sitting round a table, and instead of wholesome food which had been cooked for their consumption one saw tinned fish, tinned vegetables, and many other things which avoided the trouble of cooking. It was not only because the parents were unwilling to cook, in many instances they had never been taught how to cook. The result was that the homes of those of the industrial classes showed, more than one could wish, an under-nourishment which was partly due to their want of education in this particular. It was not due to any carelessness or to want of love for their children, because there was nothing more striking than the devotion to the children to be found in most homes in all classes in this country: it was due to want of knowledge. One of the best investments the Government could make would be to provide travelling vans to go about the country giving lessons and lectures on the choice and cooking of food. People were ready to receive such instruction, because they were beginning to understand that the choosing and cooking of food were no small matters in securing the proper nourishment of the young.

Earl STANHOPE, replying to the debate, said that the question of nutrition had been very adequately dealt with by Lord Dawson of Penn. He found himself in entire agreement with everything that Lord Dawson had said. He had not been very long in his present office, but he had already been making inquiries in the direction of which Lord Dawson spoke, and his view was that it was a question of education much more than a question of lack of money. A great deal could be done in that direction. Many people were inclined to quote the very high physical development in Germany, and yet the younger Germans were those born either during or just after the war, when the question of nutrition in Germany was one of great difficulty and when practically no children, whatever their class or wealth, had much chance of getting adequate food. The improvement had been due not to better nutrition so much as to physical training and physical development given by the sort of methods proposed under the Bill.

The Bill was read a second time.

Prevention of Silicosis

On June 29 Mr. JAMES GRIFFITHS asked the Secretary for Mines if his attention had been called to the discovery by research in Canada of a method of preventing silicosis by the use of certain dust mixtures. Captain CROOKSHANK replied that he had as yet no information except short general references in the Press. Until he had received and studied full particulars of these researches, which his Department was obtaining, he would not be in a position to make a statement.

Tuberculosis Care Committees in Wales.—Tuberculosis care committees have been established in six counties and one county borough in Wales. Sir KINGSLEY WOOD, who stated this on June 17, added that he had asked all the county and county borough councils in Wales to give early and careful attention to the provision for after-care.

Notes in Brief

The number of beds available in local authority institutions in Scotland for cases of infectious disease, including tuberculosis, was approximately 11,350 at the end of 1935 and 11,600 at the end of 1936.

Medical News

Dr. Thorvald Madsen, chief of the State Serum Institute of Copenhagen, has, for the seventh time, been elected president of the Health Committee of the League of Nations.

At a festival dinner in support of the Princess Elizabeth of York Hospital for Children, Shadwell, to be held at the Mansion House on July 15, with the Lord Mayor, Sir George Broadbridge, in the chair, the principal speaker will be the Archbishop of Canterbury.

The introductory address for the hundred and second session of the Middlesex Hospital Medical School will be given by Dr. George E. Beaumont on Wednesday, July 21, at 3 p.m. in the Scala Theatre, Charlotte Street; and the prizes will be distributed by Viscount Dawson of Penn.

The nineteenth annual meeting of the Mental Hospitals Association will be held at the Guildhall, London, on Tuesday, July 13, at 11 a.m. Papers will be read by Dr. T. C. Graves on "The Treatment of the Patient—First Things First," and by Dr. W. J. S. Reid on "The Outpatient Clinic for Treatment of Early Mental Cases."

The International Balneological Congress at Budapest has been postponed until October 7 to 14.

The postponed eleventh International Congress of Psychology will be held in Paris from July 25 to 31, with Professor Pierre Janet as honorary president, Professor Henri Pieron as president of the Executive Committee, and Professor I. Meyerson as general secretary. The headquarters of the Congress are at the Laboratory of Psychology of the Sorbonne.

Dr. George F. Buchan, medical officer of health for the borough of Willesden, was among those who received the distinction of honorary life membership of the Canadian Public Health Association conferred at its twenty-sixth annual meeting held recently in Toronto.

At Cheltenham College on Speech Day (July 3) Lord Willingdon unveiled a memorial tablet to Dr. E. A. Wilson on a wall of the new science laboratory. This bears the inscription "Edward Adrian Wilson, M.B., biologist and explorer; from boyhood a lover of Nature. He died with Scott on the return from the South Pole, March, 1912. Strong in will to strive, to seek, to find, and not to yield."

During the world exhibition at Paris 237 Congresses will be held, 18 of them medical.

The German State Medico-Historical Association intends to arrange an exhibition of medical caricatures in the autumn. Further information can be obtained from Kaiserin-Friedrich Haus, Robert Koch-Platz 7, Berlin, N.W.7.

Mr. Herbert Eason, M.S., F.R.C.S., who took up the duties of Principal of the University of London on July 1, has accepted the invitation of Lord Crewe and the committee to become a member of the Executive Committee of the British Institute in Paris in place of the late Sir Edwin Deller.

The Committee of Management of the Infants Hospital, Vincent Square, Westminster, S.W., announces that the age limit for patients at this hospital has been raised to 12 years, and that children from birth to 12 years of age are now eligible for treatment there.

The issues of the *Münchener medizinische Wochenschrift* for June 25 and of *Die medizinische Welt* for June 26 are devoted to the history of Göttingen University on the occasion of the 120th anniversary of its foundation.

The Japanese Government has recently appointed a committee to discuss the question of establishing a Ministry of Health for Japan.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Finance Department, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Finance Department.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES are
EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*
FINANCE DEPARTMENT (Advertisements, publishing, subscriptions, etc.) *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediocra Westcent, London.*

The address of the B.M.A. Scottish Office is 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 24361 Edinburgh), and of the Office of the Irish Free State Medical Union (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone 62550 Dublin).

QUERIES AND ANSWERS

Mastitis of Puberty in the Male

Dr. F. E. COOMBES (Forest Gate, E.7) writes: In connexion with Dr. W. Paterson Brown's letter (*Journal*, June 5, p. 1188), a case of mine may be of interest. A male, aged 18, had mastitis of the right breast which did not respond to treatment; he was therefore sent to a surgeon. The night before his visit he had an acute attack of abdominal pain. The surgeon found an undescended testicle in the inguinal canal. When this was dealt with the mastitis cleared up spontaneously.

Reducing by the Book

"C. W. A." writes: With reference to Surgeon Lieutenant D. P. Gurd's note (June 12, p. 1240) headed "Reducing by the Book," I should like to ask what weight the book should be? The *Medical Directory* is about 6 lb.; is this sufficient?

Income Tax

University Examiner—Travelling Expenses

"OFFICIAL" inquires whether he can deduct the cost of travelling to act as a university examiner at a fee of £20 for the academical year. The work involves staying in the university town for a day or two.

*** An examinership is technically an appointment, and the emoluments are assessable under Schedule E. The expense of travelling, etc., to the place where the duties are performed is not allowable. It was refused by the High Court (Ricketts v. Colquhoun) in the case of a barrister incurring similar expenses in connexion with an appointment as Recorder. The harshness of the rule in such circumstances was recognized in the report of the recent Committee on the Codification of the Income Tax.

Tax on Official Quarters

"W. G." is a medical officer in one of the Government services, and as such has to occupy an official residence. He cannot sublet it, and regards it not as an official emolument, but rather as the reverse. He has been assessed for tax on the "annual value" of the premises. Is that correct?

*** In similar circumstances a bank manager or other employee not in Government service would not be liable. Unfortunately the position of an individual in the service of the Crown is specifically provided for in the statutes (Schedule A, No. 7, Rule 11), and we have to advise our correspondent that he is legally liable to the tax. We may perhaps add that we understand that the amount on which the tax is payable ranks for pension, so that the Government is at least consistent.

LETTERS, NOTES, ETC.

"V.U.A."

Mrs. CLARA HARDY (7, Darley Avenue, West Didsbury, Manchester) writes: Shocked by newspaper accounts of children fatally burned through being left in a house alone, I formed the society known in London as Voluntary Unofficial Aids. These women, without any charge, mind children for short periods, visit the lonely and the sick, and escort children to hospitals, etc. There are now eight branches in different parts of the country, but London needs a new honorary organizer. There are no funds, but a certain amount of time and money is needed by the organizer. I will gladly give details to anyone willing to undertake this interesting work.

A Remedy for Hay Fever

Dr. REGINALD F. WHITE (Nailsea, nr. Bristol) writes: As a sufferer for many years with hay fever I have naturally tried all the recognized remedies, with very little or no relief, and would suggest a simple remedy which I have devised and tried with considerable success. Two small plugs of "sorbo" sponge are cut to suitable size so as to fit comfortably inside the nostrils. These are worn continually during the day and are removed only for cleansing. I have worn such plugs for a whole day without changing and without the slightest discomfort. As an added safeguard, to prevent the plugs being accidentally drawn into the nose by a sudden violent inspiration, they can be easily fastened across the septum by fine silk. I do not advise the plugs to be worn at night, but as an alternative a thin gauze mask is tied over the nostrils. The advantages of this remedy are: (1) easy and rapid cleansing; (2) minimum amount of discomfort; (3) minimum interference to respiration; (4) simple cleansing in cold water only is necessary; (5) maximum comfort and relief. My own routine consists of the above, combined with 1/4 grain of ephedrine by mouth two or three times a day. The above procedure has enabled me to do my work in comfort, and, furthermore, I have been able to enjoy the open air and sunshine, which was otherwise absolute misery.

Counting Respirations

Dr. J. P. HASTINGS (Auckland, N.Z.) writes: It is with no little diffidence that I venture to write this letter. Some time back an article appeared in the *Journal* the purport of which was to encourage general practitioners to write concerning their medical experiences. This is my excuse for bringing under your notice an auscultatory method of counting the respirations. For some years now, in diseases of the respiratory tract, I have made a practice of noting the respiratory rate by means of listening with the stethoscope for a period of at least one minute. I have found this method more satisfactory than the usual clinical procedure.

Short-wave Therapy

Dr. P. P. DALTON (London, W.1) writes: I am glad to see by Dr. H. J. Taylor's letter in your issue of June 26 that his previous letter was not intended to be a counterblast to my published work. I do not follow the rest of his letter. What D'Arsonval claimed for diathermy in 1891-6 seems to me to be as relevant as is what Gladstone said in 1888! Short-wave therapy had never been heard of in 1891-6, and what D'Arsonval then claimed for diathermy has nothing to do with what I now claim for low-intensity short-wave therapy, which is not a diathermic effect at all. I deny the statement that I am putting forward "claims" as "evidence," old or new. I have put forward "evidence" on which to base a "claim"—namely, that with low-intensity short-wave therapy "an influence has been exerted and an effect obtained." The fact that Audiat, Delherm, and Fischgold made similar claims surely does not prove my claim to be false. Dr. H. J. Taylor professes to be unable to see "that any new evidence has arisen because such claims have been made before." Surely the making of a claim does not prevent new evidence arising. He having published his opinion that short-wave therapy has no specific effect does not want, as he expressed himself to me after seeing one of my experiments, "to be forced to eat his own words"; but, as I told him in reply, "it is better that one scientist should be forced to eat his own words than that science should be deprived of knowledge." I appeal to Dr. Taylor to look at the new evidence with a seeing, not an unseeing, eye.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

22 Epidemic Myalgia and Epidemic Poliomyelitis

B. DE RUDDER (*Klin. Wschr.*, April 24, 1937, p. 585) notes that these diseases have (1) epidemiological similarities, both showing an August to September peak in the frequency curve in the northern, and a February to March peak in the southern, hemisphere; (2) a geographical distribution which is similar and "equitorifugal"; and (3) a similar variability of contagiousness in different epidemics. Clinically it has been reported that the abortive or non-paralytic form of poliomyelitis is some ten to twenty-five times as frequent in an epidemic as is the paralytic form, and that many abortive cases are associated with severe neuralgia or myalgia. The findings in the cerebro-spinal fluid in acute myalgia with meningism in children, as recently reported by Lindberg, resembled those of poliomyelitis with a mixed-cell pleocytosis, a luetic gold curve, and a normal or increased sugar content. It is suggested that the one disease may be a harmless pathomorphic variant of the other, and that testing the serum of patients convalescent from epidemic myalgia against poliomyelitis virus might be instructive.

23 Vitamin C Deficiency in Gastric Disease

W. THIELE (*Dtsch. med. Wschr.*, May 28, 1937, p. 855) maintains that the conventional treatment of various diseases of the stomach with a diet consisting exclusively of milk, eggs, rusks, white bread, etc., over a long period may be a potent cause of serious vitamin C deficiency. He has demonstrated that such a deficiency is the cause of many gastric haemorrhages. He controls the vitamin C metabolism in the body by quantitative tests of the ascorbic acid in the urine. In a consecutive series of 725 examinations of patients suffering from diseases of the stomach he has studied the excretion of ascorbic acid given parenterally or in the form of various foods rich in vitamin C. When patients were on a conventionally sloppy diet of milk, bread, etc., he found the daily excretion of ascorbic acid was often under 30 mg. The figure became higher when this diet was replaced by an ordinary one. When ascorbic acid was given by parenteral injection to patients with vitamin C deficiency, at first only a small fraction of the ascorbic acid could be recovered from the urine, but as the injections were continued the amount excreted rose, showing that the metabolism of vitamin C in the body had improved. These investigations, conducted in a public hospital in Dresden, led to the treatment of various gastric conditions with foods rich in vitamin C, such as the pressed-out juices of grapes, tomatoes, carrots, spinach, etc., in addition to the conventional dietary for such cases. In carcinoma of the stomach the excretion of ascorbic acid was found as a rule to be much below normal, and this was evidently because anacidity or achylia had interfered with metabolism of the vitamin C given in the food. The acidity of the gastric juice should therefore be determined, and if anacidity is found, the administration of vitamin C by the parenteral route considered.

24 Diagnosis of Pulmonary Tuberculosis

U. GAD (*Nord. med. Tidskr.*, May 22, 1937, p. 815) has undertaken gastric lavage on two consecutive mornings, using 300 c.cm. of water, in 271 patients admitted to a Danish hospital for tuberculosis. All these patients presented no radiological evidence of active pulmonary tuberculosis. In as many as thirty-four cases tubercle bacilli were found by this means, and the patients were classified in five groups. Out of ninety-seven patients in the first group who were admitted to hospital for observation, although the radiological picture was perfectly normal, there were eleven in whose stomachs tubercle bacilli were found. In the second group of sixty-six patients there was a history of pulmonary tuberculosis earlier in life, but the radiological picture showed no sign of active disease. The gastric lavage, however, yielded tubercle bacilli in five of these cases. In the third group of seventy-five patients suffering from pleuritis there were twelve whose stomachs contained tubercle bacilli, although in none of these cases was there any radiological evidence of a tuberculous focus in the lungs. In the fourth group of ten cases in which the radiological findings were indicative of hilus tuberculosis, but in which there was no sign of any infiltration of the lungs, there were as many as six whose stomachs contained tubercle bacilli. In the fifth and last group of twenty-three patients, representing a great variety of morbid conditions such as erythema nodosum, spontaneous pneumothorax, emphysema, bronchitis, etc., there was not one case in which gastric lavage yielded tubercle bacilli. Thus it was only in this last group that the radiological and bacteriological tests agreed in being invariably negative. The author concludes that the radiological examination of the lungs often fails to detect active pulmonary tuberculosis, and that in many cases gastric lavage repairs this diagnostic failure.

25 Dental Trigeminal Neuralgia

W. BAUER (*Wien klin. Wschr.*, May 22, 1937, p. 681) distinguishes between true trigeminal neuralgia and the neuralgia caused by dental affections, although this may in its later stages simulate the true trigeminal neuralgia. The main causes of the dental type are chronic inflammatory conditions of the dental pulp and of the paradental tissues. These affections may give rise to changes in the Gasserian ganglion. In all cases of trigeminal neuralgia a thorough examination of the teeth and jaws is indicated, particularly by means of radiology. The dental trigeminal neuralgia usually subsides after the affected teeth have been attended to; on the other hand a very severe trigeminal neuralgia may follow a dental operation in an otherwise healthy patient. These neuralgias, however, are usually cured in from three to fourteen days; *x*-ray treatment combined with aconitine therapy may be of value.

Surgery

26 Gastro-duodenal Ulcer

P. SAVY, R. FROMENT, A. CHAPUY, and M. JEUNE (*Presse méd.*, April 21, 1937, p. 609) describe the common signs and symptoms of gastro-duodenal ulcer, including pain in the epigastrium with dorsal or thoracic radiation, which appears some time after meals and is relieved by the ingestion of food. Pain usually lasts for about three weeks, with intervals of remission for several months. As a result of observation in 215 cases of peptic ulcer certain anomalies have been noted. In some cases the pain may be felt in an unusual region, such as the dorso-lumbar, and instances are given in which a duodenal ulcer caused pain of the pseudo-nephritic type or pain in the left lumbar area. Hypogastric and pseudo-intestinal types were also seen, in the first of which the pain started in the left iliac fossa and in the second in the appendicular region. In other instances the pain originated in the thoracic region before extending to the abdomen. It was noticed that in certain cases pain was not relieved by eating, and on occasion it occurred soon or immediately after taking food. Anomalies regarding the duration of the attacks were also observed: two cases are quoted in which they lasted only three days, and another

in which a period of quiescence lasting for eighteen months was followed by pain several times a day with only an interval of one or two days between. Other anomalies which may lead to a mistaken diagnosis include raised temperature, vomiting, and pain simulating that of cholecystitis. In those cases which do not present the typical symptoms of peptic ulcer radiography is necessary in order that a correct diagnosis may be made.

27 Thyroidectomy

A. SEBASTIANI (*Policlinico*, Sez. Prat., May 17, 1937, p. 953) refers to the recent paper by Antonucci (ibid., March 29, p. 601) and records his observations on nine cases of hypertension in which thyroidectomy was performed with the following results. In four cases the operation had a hypotensive effect which seemed to be permanent; in two this effect lasted for a few months and then there was a return to the pre-operative condition. In one case there was no effect, and in two there was a rise of pressure, but in one of these the patient had been taking a hypertensive drug for a long period, and in the other a retrosternal goitre was discovered. Sebastiani states that, although his series is too small to be conclusive, such a severe operation as thyroidectomy is not justifiable except in very severe cases.

28 Electro-resection in Prostatic Hypertrophy

K. SCHNEIDER (*Z. Urol.*, 1937, **31**, 5, 313) summarizes the results of resection of the hypertrophied prostate in 128 cases treated during the last three years at the hospital of the Göttingen University. The results were good in 73 per cent. and unsatisfactory in 15 per cent. The mortality amounted to 12 per cent., but whereas the mortality from electro-resection amounted to 2.5 per cent. only, that from surgical resection was 27 per cent. The mortality among patients treated by conservative means was 29 per cent. Electro-resection showed also a larger proportion of good therapeutic results than did the surgical resection. In 50 per cent. of the cases treated by electro-resection the operation was carried out in one sitting. The disadvantage of this method of treatment is that the resection is incomplete and the adenomatous tissue is left behind which may ultimately become carcinomatous. But this disadvantage is largely compensated for by the lower mortality among the patients treated in this way. Also, electro-resection can be carried out with beneficial results in patients unable to stand the strain of surgical resection.

Therapeutics

29 Serum Therapy in Scarlet Fever

H. LUTZ (*Med. Welt*, May 8, 1937, p. 641) reports on 1,659 cases of scarlet fever of which 1,127 were treated with serum and 532 symptomatically. Three types of sera were used: (1) an anti-toxic and anti-bacterial horse serum to which 0.5 per cent. phenol was added to conserve it; (2) an anti-toxic horse serum without phenol; and (3) an anti-toxic and bactericidal streptococcal serum. The best results were obtained with the first of these. The sooner the patient received serum therapy the better was the result. Seventy-three per cent. of cases showed a good or moderately good result when injected on the first day, but this was reduced to only 20 per cent. when injections were given after the fourth day of the disease. Patients treated with serum had a normal temperature and no rash usually about twenty-four hours sooner than non-treated patients. The effect of serum treatment in the second stage was not marked. The most common complication, lymphadenitis, was found in 50 per cent. of treated and non-treated cases. Lutz believes, however, that complications in treated cases ran a milder course than those in non-treated cases. Serum disease occurred in 10 per cent. of cases. Serum therapy did not appear to influence the mortality rate, which in treated cases was 1.1 per cent. and in non-treated cases 1.7 per cent. The author advises the administration of serum in every case of scarlet fever admitted within the first four days of the disease, and in those in which the temperature has not fallen to normal on admission. 25 c.cm. of serum are injected intramuscularly in adults and 10 to 15 c.cm. in children.

30 Gonococcal Arthritis

P. LOUP (*J. Urol.*, March, 1937, p. 238) refers to the serious complications, reported by Dr. Marsan, which have followed the introduction of radio-active substances, particularly when intravenous injections of thorium X have been given, in cases of gonococcal arthritis. Anaemia has sometimes resulted, and in one instance a patient developed an osteosarcoma of the right femur, from which he died, several years after intravenous injections of thorium X had been given. Two personal cases are reported in which this treatment was successful and without complications up to the present. In the first a young man, aged 19, was suffering from a severe attack of gonorrhoea which was affecting the joints of the hand. A subcutaneous injection of anti-gonococcal serum was given with success. The patient only attended irregularly and returned after several days with severe arthritis of the right knee, which was swollen, painful, and useless. Further injections were given and local treatment applied, but the condition of the knee became steadily worse. Intravenous injections of a solution of thorium X were given, and the knee, which had been ankylosed before the injections began, could soon be flexed to a right angle, and after three months' movement was completely normal. Seven years later the patient was in perfect health with no disability of the knee-joint. In the second instance a woman, aged 28, had been receiving an intravenous injection of "gonocrine" every other day, but in spite of this a typical arthritis developed in the wrist with a synovitis of the right thumb. Anti-gonococcal serum was given daily without any effect on the arthritis, and so injections of the same solution of thorium X were tried, with the same good result as in the former case. After three years the patient was still in good health. The danger of this form of treatment as emphasized by Dr. Marsan is a strong deterrent to its universal use.

Neurology

31 Acute Primary Polyneuritis

S. DRAGANESCO and E. FAÇON (*Paris méd.*, May 8, 1937, p. 411) describe a series of cases of acute primary neuritis, of unknown origin, which occurred in Rumania, and almost amounted to an epidemic. The onset was of an acute nature, but the symptoms and development of the disease did not appear to be connected with any particular infection such as poliomyelitis or encephalitis lethargica. The majority of the patients were between the ages of 20 and 50. The first symptoms were those of a general feverish attack which lasted for three to five days, and was followed by paraesthesia of the limbs, particularly in the distal parts, with sharp pain radiating along the course of the nerves. In the majority of cases there were motor disturbances in the lower limbs with partial or complete paralysis. The cranial nerves were affected in some cases, and in three instances evidence of an ascending paralysis was found. The tendon reflexes disappeared in the affected areas. The skin reflexes were usually abolished and pressure over the muscles caused acute pain, while difficulty with micturition was sometimes present. In the majority of the cases the condition lasted from three to five months, and in nearly every instance there was a complete recovery with no sequelae. Examination of the cerebro-spinal fluid showed typical changes with albumino-cytologic dissociation and sometimes an increase in the albumin and globulins present. It is thus evident that

the meninges were involved in the pathological process. The Wassermann reaction was negative. It is considered that this was a primary infection of the nervous system due to an ultra-virus acting on the peripheral nerves through the nerves themselves, the spinal ganglia, or the nerve roots. Thirteen cases are reported, in all of which recovery took place.

32 Hypothalamus in Diabetes Mellitus

L. A. MORGAN *et al.* (*J. nerv. ment. Dis.*, February, 1937, p. 25) describe constant changes which they found in the hypothalamus in cases of diabetes mellitus. The brains of fifteen diabetic patients were compared histologically with those of five controls. A personally modified iron haematoxylin stain was used and special attention was paid to the cells in the region of the third ventricle. It was found that the nucleus paraventricularis showed definite pathological changes in all the fifteen cases examined. There was marked loss of nerve cells, which averaged 40 per cent. of the normal throughout the series. The changes were diffuse throughout the nucleus; the cells that remained showed all stages of chromatolysis; only a small proportion could be classed as normal. Changes in the other hypothalamic nuclei were inconstant, but in six cases the substantia grisea and the nucleus tuberis lateralis showed cell damage. It is remarkable that Morgan and Gregory have found similar alterations in these nuclei in cases of psychosis, and that in five of the six cases described definite mental changes were also observed. The relation of these pathological findings to the other evidences of a centre in the hypothalamus regulating carbohydrate metabolism is discussed.

33 Paroxysmal Trigeminal Pain due to Acoustic Neuroma

H. L. PARKER (*J. Neurol. Psychopath.*, January, 1937, p. 256) records two cases of acoustic neuroma in which very severe pain was complained of. The pain was paroxysmal and simulated true tic douloureux very closely. It was situated in the distribution of the second and third division of the trigeminal nerve. In one case an injection of alcohol relieved the pain completely. It is observed that pain exactly simulating tic douloureux has been described in cases of disseminated sclerosis, and plaques have been demonstrated in two of these cases at the root entrance zone of the fifth nerve on the side of the pain. Here also the pain was relieved by alcohol injections or by fifth nerve section. In trigeminal neuralgia the cause of the pain is unknown, although Harris's postulate that it is due to septic neuritis of the terminal filaments of the nerve has been widely accepted. In acoustic neuroma and in disseminated sclerosis a definite site of damage to the nerve can be demonstrated, and an identical pain is produced and relieved. It is suggested that in all these conditions a state of exaggerated excitability of the fifth nerve exists, and that the explosion of pain depends entirely on comparatively slight incoming stimuli, which are abolished by section of the nerve, even if the nerve section is distal to the position of damage to the nerve. When this pathological state of hyperexcitability exists something in the nature of facilitations may occur in the nerve fibres to translate trivial peripheral stimulation into excruciating pain.

34 Meningeal Reactions

E. BOZZI (*Ann. Oto-laryng.*, February, 1937, p. 98) discusses the many methods which have been recommended in the treatment of brain abscess, from free incisions of the dura to drainage by needle puncture. The main preoccupation of surgeons has been (1) to cause the formation of adhesions of the dura, arachnoid, and pia mater round the surface area through which the abscess has to be reached; and (2) not to interfere with any protective adhesions which have already formed in the course of the disease process. The author experimented with rabbits and studied the defensive reactions of the meninges and of the cerebral substance in the presence of rubber tubes, acting as foreign bodies. In a first series of animals a circular piece of bone with a diameter of 1 cm. was removed from the parietal bone. The dura was pierced by an ordinary Record syringe needle, which was pushed into the brain substance for a distance of 7 to 8 mm. A hollow sound was then substituted, and finally a small rubber tube. This procedure imitates the operative technique of Lemaitre. In a second series of rabbits a small tampon soaked in a 10 per cent. solution of tincture of iodine was placed against the dura for forty-eight hours. After this time had elapsed the dura was pierced and the drainage tube placed in position. In a third series much larger pieces of bone were removed, the dura was incised by a fairly large cross-shaped incision, and two drainage tubes were placed in position side by side. In a fourth series the author used the iodized tampons for forty-eight hours before practising the large incision. The surviving animals were killed after eight days, and the condition of the meninges and brain round the drainage tract was examined histologically. The animals of the first and second series had survived in good condition. Those of the third series usually died thirty-six hours after the intervention, with signs of encephalitis and meningitis, a large cerebral hernia forming and extruding the drainage tube. Those of the fourth series were alive after forty-eight hours, and the tube was maintained in position in spite of some encephalitis and herniation.

35 Surgery of Cerebral Apoplexy

A. KAPLAN (*N. Y. St. J. Med.*, May 15, 1937, p. 934) points out that cerebral apoplexy may occur in patients without hypertension, syphilis, or renal disease. If the intracerebral haemorrhage is small they may live for years handicapped by a residual paralysis, if large they succumb to the initial vascular disturbance. Although in the latter surgical intervention is rarely considered, Kaplan has found records of several cases in the literature in which recovery followed operation. He adds two successful cases of his own, which were operated on because of a remote possibility of subdural haematoma following trauma in one case, and because cerebral abscess, neoplasm, or thrombosis was suspected in the other. The differential diagnosis between cerebral haemorrhage and thrombosis is not always easy, and the author lays stress on the following points: cerebral haemorrhage is most frequent between 40 and 50; it is commonly heralded by sudden severe headache or vomiting; the progression of signs is more frequent in it, and coma and convulsions are twice as frequent as in cerebral thrombosis; stiffness of the neck and increased cerebro-spinal pressure (over 300 mm.) is very much more common in cerebral haemorrhage; peripheral and retinal arteriosclerosis is further advanced in cerebral thrombosis. Kaplan concludes that the criteria for surgical intervention in cases of cerebral haemorrhage are still indefinite, but it is justifiable in young or middle-aged patients who survive for twenty-four to forty-eight hours and whose symptoms are progressing. It is contraindicated in those with advanced hypertension or renal disease, or those with massive haemorrhage as revealed in the cerebro-spinal fluid. A preliminary ventriculogram for precise localization of the lesion is advisable before operation.

36 Neurological Complications of Vaccines and Serum Therapy

L. J. ROBINSON (*New Engl. J. Med.*, May 13, 1937, p. 831) states that, although rare, neurological complications following the administration of every type of vaccine and serum have been described. He reports fully a personal case of peripheral nerve paralysis after the prophylactic administration of T.A.B. vaccine. The usual clinical picture is that of a lower motor neurone paralysis occurring between one and sixty days after the injection. Any peripheral or cranial nerves, and less commonly the spinal cord or higher centres, may be affected. Serum sickness,

urticaria, and atrophy may be present, but are not invariable. Residual paralyses persist in a large number of cases. Central nervous system involvement may show itself in the form of an anaphylactic response, some bizarre nervous manifestation, or some typical clinical picture of central nervous system disease. The prognosis is guarded as to recovery in peripheral involvement, and bad in central nervous system involvement. In the differential diagnosis anterior poliomyelitis, lead poisoning, diabetes, alcoholism, avitaminosis, and diseases of the cord and higher centres must be borne in mind. The exact aetiology of these neurological complications is unknown. It was thought that they were due to perineural oedema, a foreign protein reaction, a specific neurotoxin, or a local manifestation of an attenuated virus disease. The author thinks that they may be due to phenol, which is the preservative used in vaccines and sera, and the effect of which is almost entirely confined to the central nervous system. Necropsy material is scanty and the findings varied and inconclusive. Neurological complications cannot be foreseen, but should not contraindicate the administration of vaccines or sera. When they do occur rest is indicated in the early days, followed by infra-red therapy, gentle massage, passive then active movement, and, later, interrupted negative galvanic current.

Obstetrics and Gynaecology

37 Oestrin in the Urine

B. QUENTAL (*Ann. bras. Ginec.*, April, 1937, p. 307), employing Siebke's technique, showed that the excretion of oestrin in the urine passed between the thirteenth and seventeenth day of the intermenstrual period by sixteen women, aged from 18 to 32, with a normal menstrual rhythm, varied from 116 to 164 mouse units in the twenty-four hours. In four cases of primary amenorrhoea he found that the excretion of oestrin was lowered to less than 60 units; in each of thirty-eight cases of secondary amenorrhoea, the duration of which had varied from a few months to a few years, the excretion of oestrin was lowered; and in twenty-three cases of oligomenorrhoea the excretion was also diminished. In three specimens of urine from cases of excessive menstruation 460 units were found in the first, 612 in the second, and 244 units in the third.

38 Menstruation after Hysterectomy

H. FUCHS (*Zbl. Gynäk.*, May 1, 1937, p. 1027) describes successful results in the preservation of menstruation after supravaginal amputation (1) by the insertion of a free endometrial transplant in the cervical wall, and (2) by the implantation of a Fallopian tube in the cervical canal. The first method is specially suitable when the oviduct is diseased and unavailable for transplantation, the latter when the corporeal endometrium is unhealthy. The true menstrual nature of the cyclical bleedings which follow in the second case is open to discussion, although considerable evidence pointing to tubal menstruation has lately been forthcoming; practically, however, it ensures that the patient escapes a "psychical trauma." The endometrial transplant is sutured to a freshened area of the posterior cervical wall by stitches passing through the whole of the latter and uniting it to the posterior surface of the stump; all are covered by vesical peritoneum with the object of preventing subsequent ectopic gestation. When this procedure is chosen it is important to exclude the possibility of malignant disease. Careful examination of both corporeal endometrium and cervical epithelium should be made and should include a microscopical examination if the appearances arouse suspicion. This transplantation was followed by regular periods in thirteen out of twenty-three cases and by irregular menstruation in six, although the average age was 41, and half of these myoma-bearing patients had ovarian cysts or other benign ovarian tumours. Fuch's second method —namely, cervical implantation of a Fallopian tube—is similar to Strassmann's tubal grafting into the amenorrhoeic atrophic uterus. Strassmann's operation was successful in all his six cases, whereas Fuchs had four satisfactory results in seven patients of an average age of 39.

Pathology

39 Cerebro-spinal Meningitis

T. PACKALÉN (*Finska LäkSällsk. Handl.*, April, 1937, p. 313) gives an account of an outbreak of cerebro-spinal meningitis in a guards regiment in Viborg, where he undertook bacteriological examinations of the patients and their contacts, as well as of non-contacts. It was significant that meningococci were found with equal frequency in the throats of healthy soldiers whether they were contacts or non-contacts, old soldiers or raw recruits, officers or men. In 111 contacts the incidence of the carrier state was 43 per cent., whereas it was 40 per cent. for the 156 non-contact soldiers, 44 per cent. for old soldiers, 40 per cent. for recruits, and 37 per cent. for officers. While the frequency of the carrier state in Viborg was invariably high, ranging from 37 to 45 per cent., a search among soldiers and medical students in Helsingfors showed only 10 to 12 per cent. to be carriers. In all the cases of cerebro-spinal meningitis the meningococci found in the cerebro-spinal fluid and throat conformed to the characteristics of the English types I or III; and while the meningococci found in two-thirds of the contacts belonged to one or other of these two types, this was the case with only about 3 per cent. of the meningococci found in non-contact carriers. The strains cultivated from the throat which did not belong to one or other of these types could not as a rule be found to correspond to any other English type. The author considers that these at present unclassifiable strains may be regarded as more or less avirulent.

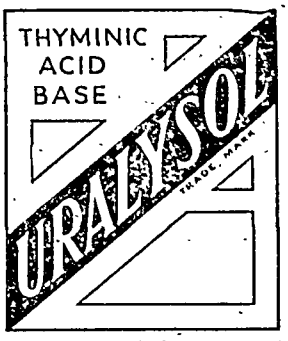
40 Sclerodermia

R. GANTENBERG and H. ROSEGGER (*Med. Welt*, May 1, 1937, p. 597) believe that only the careful reporting of individual cases will elucidate the complicated pathogenesis of sclerodermia with its manifold symptoms. Sclerodermia has been held to be due to (1) a lesion of the central nervous system with damage to the nervous supply of superficial blood vessels; (2) a lesion of the superficial blood vessels themselves; (3) peripheral neuritis; (4) endocrine dysfunction—namely, hyperparathyroidism; (5) metabolic dysfunction—namely, disturbance of fermentation in the gastro-intestinal canal; and (6) infection following focal sepsis, scarlatina, etc. The authors report one case of localized and one of generalized sclerodermia. In both cases the condition began with acrocyanosis. The fingers became cyanotic, then pale, and later red. Sensory disturbances were marked, and finally the fingers were thickened and the patients experienced difficulty in closing the fist. In both cases pigmentation occurred. In the case of generalized sclerodermia subfebrile temperatures were found. In both chronic inflammatory changes were present which were regarded as non-specific allergic reactions. Eosinophilia was found in both cases. Hypercalcaemia was not observed in either case, nor any abnormal changes in the blood chemistry. The values of Weltmann's coagulation test were increased, denoting cirrhotic changes. The authors believe that this may be a valuable test in the differential diagnosis between sclerodermia and other forms of acrocyanosis. Dysfunction of anterior pituitary and ovary were noted in both cases. The authors believe that their two cases tend to confirm the allergic, infectious, and endocrine theories of pathogenesis rather than the neuritic and metabolic.

LONDON HOSPITAL CATGUT

Reveals all the advancements achieved through Modern Research

It is an achievement of modern British research made entirely by British labour, and is specified by leading surgeons throughout the world



LONDON HOSPITAL CATGUT WILL BE ON DISPLAY AT THE B.M.A. EXHIBITION AT ULSTER HALL, BELFAST, FROM JULY 19th TO 23rd INCLUSIVE

LHC

Specify

LONDON HOSPITAL CATGUT

OBTAINABLE FROM ALL LEADING SURGICAL EQUIPMENT HOUSES

FORMULA

Thyminic Acid	0·10
Hexamethylenetetramine Anhydromethylenecitrate	0·50
Hexamethylene Tetramine	2·50
Piperazine Tartrate ..	0·25
Lithium Carbonate ..	1·00
Sodium Benzoate. ..	1·00
Effervescent Base ..	ad 100

DIRECTIONS

One teaspoonful to be taken morning and night in a tumblerful of water.

Uralysol, in addition to being a solvent and eliminator of pathological Uric Acid, is a powerful urinary antiseptic.

Normally there exists in the body a certain quantity of uric acid, which assists general metabolism, and after it has played its part is eliminated together with the normal thyminic acid of the organism. When, however, uric acid is present in excess, the body needs additional thyminic acid to supplement the resultant deficit of this normal solvent of uric acid.

Uralysol, by its thyminic acid content, supplies the agent necessary to dissolve excessive uric acid.

The next step is the elimination of this thyminic-uric acid which, being in excess of normal, necessitates treatment by an agent capable of enhancing elimination.

Uralysol, by its content of hexamethylenetetramine and lysidin, stimulates the organism to eliminate the pathological uric acid already dissolved by its thyminic acid content.

HOW IMPORTANT
ARE MINERALS IN THE DIET?

?

They are absolutely essential for the maintenance of an adequate state of nutrition. However, not infrequently an apparently minor mineral deficiency may weaken the body's defensive mechanism to such a point that

Pregnancy, Infection, or any other unusual tax

may lead to a prolonged period of convalescence.

!

MILK INTOLERANCE

Benger's Food is devised to be used in conjunction with fresh cow's milk. For many years it has been used by Physicians everywhere as a routine diet in gastric cases and in cases of milk intolerance. In its composition Benger's differs from all other foods, e.g., in addition to its base of specially treated wheaten flour it contains the two natural digestive principles—Amylopsin and Trypsin—in a latent state. These exert their digestive powers during preparation. The Amylopsin acts on the carbo-hydrates and gradually changes them into soluble sugars, while the Trypsin acts on the gluten of the flour, and on the proteins of the milk. The prepared Benger's Food forms a fine soft flocculent curd in the stomach, in marked contrast to the large indigestible curd formed by milk. *The extent of the self-digestive action of Benger's Food can be varied to suit the patient's condition, and it is important to note that complete pre-digestion can never take place.*

Benger's Food contains no preservatives. It is palatable and quite free from rough irritant particles.

A Physician's sample will be sent post free to any member of the Medical Profession.

THE LANCET describes it as "Mr. Benger's admirable preparation."

SUMMER COLDS

The Summer season in Great Britain is, fortunately, free from epidemics of coryza associated with serious sequelæ. Owing to our fickle climate "summer colds" are, however, fairly widespread and cause considerable inconvenience to the victims. People returning to the germ-laden atmosphere of towns after spending holidays at the seaside or in the country often succumb to attacks of coryza which off-set, to some extent, the beneficial effect of the holiday.

Since GENORA brand ORAL VACCINE for COLDS and INFLUENZA was introduced to the Medical Profession, experience has shown that a course of this vaccine establishes a high degree of immunity. It is particularly suited for the prevention and treatment of "summer colds," as the product is taken by the mouth and thus obviates the inconvenience associated with hypodermic injections. Clinical results and laboratory tests demonstrate that the antibody response is cumulative as the agglutinin titre rises week by week.

For cases with a history of frequent coryza and chronic bronchitis, we recommend giving the Oral Vaccine at regular weekly intervals over a considerable period, the dose ranging from 10 c.c. to 20 c.c. according to circumstances. By this method an immunity to colds is gradually built up and bronchitic symptoms materially decrease.

Additional information regarding GENORA brand ORAL VACCINE for COLDS and INFLUENZA will gladly be supplied on request.

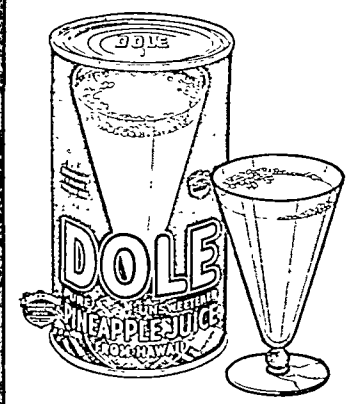
QUESTIONS and ANSWERS



Doctors have asked many questions concerning Dole Hawaiian Pineapple Juice since this natural unsweetened beverage was introduced to Britain. We are always pleased to answer questions personally, but for your convenience we have listed those asked most frequently.

1 *Is it a by-product? What do you add to it? Water? Sugar?*
It's far from being a by-product. The juice is extracted from sun-ripened Dole-grown Hawaiian pineapples. The exclusive Dole Fast-Seal Vacuum-Packing Process brings it to you field-fresh, with no added sugar, no preservatives.

2 *Where can I buy it?*
At nearly all grocers.

3 *Is it good for babies?*
Yes, it's an item of infant diets in many hospitals. It is easily digested and assimilated. Here's a typical analysis of Dole Pineapple Juice.

Moisture	85.3%
Ash	0.4
Fat (ether extract)	0.3
Protein (N×6.25)	0.3
Crude fibre	0.02
Titratable acidity as citric acid	0.9
Reducing sugars as invert sugar	12.4
Carbohydrates other than sugars (by difference)	0.38

"AMARATONE"

(A REALLY EFFECTIVE TONIC)

A most agreeable and effective aromatic bitter Tonic combining the Hypophosphites of Calcium, Potassium, Manganese, Quinine, and Strychnine with the aromatics Gentian, Orange, Quassia, etc. This preparation is extremely effective in such conditions as depression, mental and physical lethargy and inertia, especially where these arise from digestive sources, rapidly overcoming these conditions and restoring tone generally.

Price : 1/8 per lb. Winchester Lots 1/6 per lb.

"EUPINAL"

(IODIDE OF CAFFEINE)

Combining the therapeutic properties of caffeine and of the iodides in a specially elegant and effective form, "EUPINAL" is being increasingly adopted in cases of asthma, chronic bronchitis, and in affections of the cardiovascular system. It is free from toxicity, has no cumulative effect and is well tolerated even when pre-cribed over long periods. A fully descriptive booklet dealing with the Pharmacology, etc., of "Eupinal" is available upon request.

MAW STEROTHERM

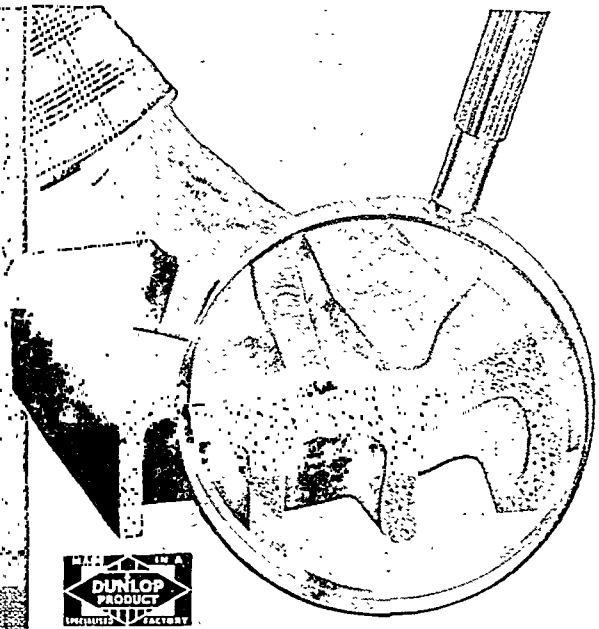
HOT AIR ELECTRIC AUTOMATIC STERILIZER

Patent No. 427581

Maw Sterotherm Automatic Sterilizers have been installed in the London, Westminster and many other Hospitals, Surgeries, etc., throughout the country and are functioning with the utmost efficiency. The special features of the Sterotherm ensure complete sterilization of Instruments, Dressings, Oils, etc., by the Hot Air method. It is the ideal unit where economy of space and outlay are essential.

May we send you details or arrange a demonstration?

SPECIAL FEATURES



- Efficient Sterilization.
- Automatic regulation of temperature.
- No supervision necessary while in use.
- Very small current consumption.
- Articles in apparatus remain sterile until required, as closure is bacteria proof.
- Dressings quite dry after leaving Sterilizer.
- Convenient size—length 16½in., diameter 9½in.

A Spa that is different...

Rheuma Spa of Wales

KINMEL HALL
ABERGELE - NORTH WALES

THIS Spa with its complete residential amenities, its 1,000 acres of gardens and grounds near the sea, its dry, sunny climate and its exceptional recreation facilities, offers recuperative advantages quite different from those of any other British or Continental Spa.

Here are the most modern treatments for rheumatic and similar disabilities under the supervision of a fully-qualified Resident Physician.

The cuisine is first-class and skilled attention is given to special diets.

WRITE FOR BROCHURE.

A handsome brochure, sent post free, containing many photographs, together with details of Spa treatments, particulars of own golf course, tennis courts, squash, badminton, riding (hunting or hacking), own trout fishing, open-air swimming pool and attractive country club (licensed). Write to Secretary.

Directors: G. E. Lindley, Mus.D., and Mrs. Lindley.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY

President. THE MOST HON. THE MARQUESS OF EXETER C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble, temporary patients, and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including *Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche*, Electrical bath Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray room, an Ultra-Violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation Therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, Llantairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate, a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts) croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton), who can be seen in London by appointment.

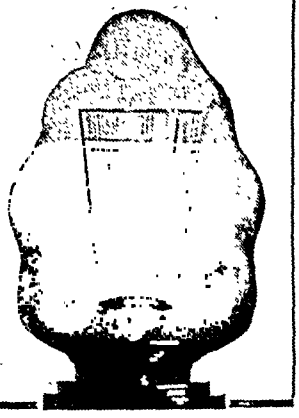
Choose a Spa in Czechoslovakia...

The Spas and Health Resorts of Czechoslovakia, with their centuries-old tradition of healing, reinforced by the experience and researches of local specialists, invite your serious consideration.



In addition to places of world-wide repute such as:

PISTANY (Piestany) **CARLSBAD** (Karlovy Vary) **MARIENBAD** (Mariánske Lázne) **FRANZENSBAD** (Frantiskovy Lázne)

ST. JOACHIMSTHAL (Jachymov) **TEPLICE-SANOV** (Teplitz-Schönau) **LUHACOVICE** **SLIAC.** **TRENCIANSKE-TEPLICE**

with their medicinal springs and mud baths, there are numerous smaller spas and health resorts admirably equipped for the treatment of many diseases, including those in the following groups:

ANAEMIA AND CHLOROSIS
BASEDOW'S DISEASE.
BRONCHIAL CATARRH.
CONSTITUTIONAL DISEASES. SCROFULA, RICKETS.
DIGESTIVE DISEASES.
DISEASES OF THE BLADDER AND URINARY ORGANS.
DISEASES OF THE KIDNEYS.
DISEASES OF THE NOSE AND THROAT.
DISEASES OF WOMEN.
DISORDERS OF BONES, MUSCLES, AND JOINTS.
DISORDERS OF THE HEART.
DISORDERS OF METABOLISM AND GOUT.
GALLSTONES.
LEUCAEMIA.
NERVOUS DISEASES AND POST HEMIPLEGIC CONDITIONS.
TUBERCULOSIS OF THE LUNGS.

The arrangements in the bath establishments are up-to-date in every way, the cleanliness and neatness proverbial, the service attentive and courteous

It is accepted that a spa cure to be fully beneficial should provide a complete change of surroundings, and a break with the patient's normal everyday life.

The Czechoslovak Spas fulfil this purpose admirably . . . comfortable hotels . . . first-class orchestras and dance bands . . . every facility for sport—tennis, golf, swimming, riding, fishing, etc.

There are also numerous fully up-to-date homes for convalescence and rest cures.

For travel information, descriptive brochure, etc., apply to:

GOVERNMENT OF INDIA

Applications are invited for the appointment of DIRECTOR OF THE ALL-INDIA INSTITUTE OF HYGIENE AND PUBLIC HEALTH, CALCUTTA. The Director also acts as Professor of Hygiene and Public Health Administration.

A Diploma in Public Health of a recognized University and ability to teach the subject of Hygiene in its widest aspects are essential qualifications.

The appointment will be made on agreement for five years in the first instance, extensible on such terms and for such periods as the Government may decide. Pay Rs. 2,500 (£2,250 per annum approx.), rising by biennial increments of Rs. 50 to Rs. 2,750 a calendar month (£2,475 per annum approx.) plus Overseas Pay of £13 6s. 8d. a month. Free passage to India and return on satisfactory termination of services. Provident Fund. (Return passage and Overseas Pay admissible only to officer of non-Asiatic domicile.) Rupee = 1s. 6d. approx.

Applications will be accepted from officers of the Indian Medical Service and of Provincial Services under Government in India, in respect of whom special conditions will apply.

Further particulars and forms of application may be obtained, on application by postcard, from the High Commissioner for India, General Department, India House, Aldwych, London, W.C.2. Last date for receipt of applications July 24th, 1937.

MEDICAL RADIOLOGY.

DIPLOMA COURSES

ST. BARTHOLOMEW'S HOSPITAL,
E.C.1.

A complete course of study for:—

(a) The ACADEMIC DIPLOMA of MEDICAL RADIOLOGY, University of London, and

(b) The DIPLOMA of MEDICAL RADIOLOGY, Conjoint Board,

is held annually at St. Bartholomew's Hospital, E.C.1. The course, which covers both Part I and Part II of the examination, begins in October each year and occupies nine months.

FEE : 50 Guineas. As the number of students that can be taken is limited, applications for admission should be made soon. They should be addressed to the Dean, St. Bartholomew's Hospital, E.C.1.

BOROUGH OF LUTON.

ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOLS MEDICAL OFFICER.

Applications are invited from registered medical practitioners for the above-mentioned appointment, at a *commencing* salary of £500 *per annum, rising* by annual increments of £25 to £700 per annum, with a car allowance of £40 per annum.

Applicants must hold the diploma of Public Health and have had experience in infectious diseases work. Experience in school medical and child welfare work will be an advantage. The duties will be largely clinical, but the post will offer an opportunity for experience in all the usual *public health duties.*

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the successful applicant will be required to pass satisfactorily a *medical examination.*

Forms of application and full particulars relating to the appointment may be obtained from the undersigned, to whom applications, together with copies of three recent testimonials, enclosed in an envelope endorsed "Assistant Medical Officer of Health," must be delivered not later than Tuesday, July 20th, 1937.

Canvassing, directly or indirectly, will disqualify.

Town Hall, W. H. ROBINSON,
Luton. Town Clerk.
July 7th, 1937.

LIVERPOOL ROYAL INFIRMARY.
(Medical School. 336 Beds.)

Applications are invited for the whole-time appointment of MEDICAL TUTOR AND REGISTRAR as from October 1st, 1937.

Salary £200 per annum.

Applications, giving details of academic qualifications and experience, should be sent to the undersigned.

WM. RUTTER,
Gen. Supt. and Sec.

COUNTY BOROUGH OF OLDHAM.

THE MUNICIPAL HOSPITAL.

RESIDENT SURGICAL OFFICER.

Applications are invited from fully qualified *Medical Practitioners for the position* of *Resident* Surgical Officer at the Municipal Hospital

The appointed candidate will work under the direction of the Medical Superintendent and the Visiting Surgeons.

The duties are mainly surgical (general) and emergency), and preference will be given to candidates possessing the F.R.C.S. or other higher surgical qualifications and previous surgical *experience.*

The appointed candidate will deputise for the Medical Superintendent when required, and undertake such duties as the Council may direct

He must devote his whole time to the duties of the office, and will not be allowed to engage in private practice.

The salary will be at the rate of £500 per annum, rising by annual increments of £25 to £550, together with board-residence and laundry. All fees and emoluments of every kind whatsoever must be handed over to the Corporation.

The appointment is for a period of two years, and is terminable by two months' notice on either side. It is also subject to the passing of a satisfactory medical examination

Applications, stating age, qualifications and experience, together with copies of three recent testimonials, should be forwarded to the Medical Officer of Health, Town Hall, Oldham, and endorsed "Resident Surgical Officer," so as to reach him not later than July 26th, 1937.

Canvassing in any form will be a disqualification.

JOSEPH J. WILLIAMS, LL.D.
Town Hall, Town Clerk
Oldham.
July 5th, 1937.

BRIDGEND URBAN AND PENYBONT RURAL DISTRICT COUNCILS.

JOINT APPOINTMENT OF ASSISTANT MEDICAL OFFICER OF HEALTH FOR MATERNITY AND CHILD WELFARE.

The above Councils invite applications from fully qualified medical men or women for the post of whole-time Assistant Medical Officer for Maternity and Child Welfare work.

Candidates should have had three years' (at least) experience in the practice of their profession and special experience in

(a) Child Welfare
(b) Ante-natal work,

subsequent to qualification.

It is desirable that candidates should have—
(1) had experience in general practice,
(2) a diploma in Public Health.

The salary will be at the rate of £360 per annum, rising by increments of £25 per annum to £700 per annum. Two-thirds of the salary will be subject to a deduction of 5 per cent. in accordance with the provisions of the Local Government and Other Officers' Superannuation Act, 1922. Travelling expenses in the Penybont area will be paid by the Penybont Rural District Council.

The person appointed will be required to give his or her whole time to the work, and must not engage in general practice.

The appointment will be determinable by three months' notice on either side.

Applications, on forms to be obtained from me at the address below, are to be received by me at the same address not later than 10 a.m. on Monday, July 19th, 1937.

By Order,
Penybont Offices, W. E. BEVAN,
Coity Road, Clerk to the Penybont
Bridgend, Glam. Council.
July 5th, 1937.

ROYAL NAVAL MEDICAL SERVICE.

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in October, 1937.

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years in the first instance, which may be extended to five years at the discretion of the Admiralty.

At the end of three years' service officers may retire with a gratuity of £400, but those who serve for five years will receive £1,000.

At the end of five years' Short Service permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Opportunities are available for officers on the permanent list to specialise, and ample provision is made for Post-Graduate study.

Copies of the regulations for entry and conditions of service, including rates of pay and allowances, may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than August 31st, 1937.

THE KING EDWARD VII WELSH NATIONAL MEMORIAL ASSOCIATION.

ASSISTANT TUBERCULOSIS MEDICAL OFFICER (Resident).

Applications are invited from duly registered medical practitioners (male, single) for the post of Assistant Tuberculosis Medical Officer (Resident) at the Sully Hospital, Sully, Glam. (300 beds for the treatment of pulmonary tuberculosis), situate between Penarth and Barry.

Salary £500 per annum, rising by annual increments of £25 to £700 per annum, less the value of emoluments amounting to £100 per annum.

Preferably candidates should have had six months' resident experience in a special institution (hospital or sanatorium) for the treatment of pulmonary and/or non-pulmonary tuberculosis, with eighteen months' experience in general clinical work, of which six months should have been spent in a hospital not confined to the treatment of tuberculosis. Experience in anaesthetics also desirable.

The person appointed to the above post will be required to pass a medical examination and to contribute 5 per cent. of his salary to the Superannuation Fund of the Association. Applicants not already in the service of the Association must be under 45 years of age.

Applications, stating age, qualifications, experience, etc., together with copies of three recent testimonials, should reach the undersigned not later than Thursday, July 15th, 1937.

Memorial Offices, Westgate Street, Cardiff. D. A. POWELL, Principal Medical Officer.

DURHAM COUNTY AND SUNDERLAND EYE INFIRMARY.

HOUSE SURGEON wanted; outdoor; from middle August. Must have ophthalmic experience. Salary £350, rising by annual increments of £50 for two years.

Applications, with copies of three recent testimonials, to be sent to JOHN BUTTERFIELD, Secretary, Eye Infirmary, Stockton Road, Sunderland.

MERTHYR GENERAL HOSPITAL. (118 Beds.)

RESIDENT HOUSE SURGEON required for a period of six months.

Salary at the rate of £150 per annum, with board and laundry. Applications, stating age, nationality, qualifications and accompanied by three (copies only) recent testimonials should be addressed to the Secretary of the Merthyr General Hospital on or before July 20.

CITY OF PORT-OF-SPAIN.

APPOINTMENT OF A MEDICAL OFFICER OF HEALTH.

The Port-of-Spain City Council invite applications for the post of Medical Officer of Health for the City of Port-of-Spain.

The duties of the office are as set forth in the bye-laws made by the Central Board of Health and published in the Trinidad Royal Gazette of October 25th, 1917, page 1975-77.

Every applicant must be, or entitled to be, a member of the Medical Board of Trinidad and shall be the possessor of a Diploma of Public Health, Sanitary Science or State Medicine, registered or entitled to be registered in Great Britain and Ireland.

The office is a whole time one and pensionable under the provisions of the Municipal Corporations (Pensions) Ordinance, No. 29 of 1936. The salary attached to the post is £800 per annum, rising by equal annual increments of £25 to £1,000, with a travelling allowance of £75 a year.

The person appointed will be required to furnish a bond in the sum of £100 for the due performance of his duties.

Applications, stating age, qualifications and experience, should reach the undersigned at the Town Hall, Port-of-Spain, Trinidad, B.W.I., not later than July 31st, 1937.

The Town Hall, Port-of-Spain, Trinidad, B.W.I. April 29th, 1937. E. PRADA, Town Clerk.

GLOUCESTERSHIRE JOINT COMMITTEE FOR TUBERCULOSIS.

Standish House Sanatorium, Stonehouse, Glos.

Applications are invited from registered medical men for the post of JUNIOR ASSISTANT MEDICAL OFFICER at the above Institution. No previous professional experience is necessary.

There are at present 250 beds, including men, women and children. There is an orthopaedic block.

The salary is £250 per annum, with board, furnished apartments, and laundry in addition.

The appointment is for six months (with the possibility of extension for a further period of six months), and may be terminable within that period by one month's notice on either side.

Applications, stating qualifications and age, and accompanied by copies of three recent testimonials, should be received not later than July 14th.

Shire Hall, Gloucester. RICHARD L. MOON, Clerk of the Joint Committee. June 24th, 1937.

COUNTY BOROUGH OF CROYDON.

PUBLIC HEALTH DEPARTMENT.

APPOINTMENT OF ASSISTANT MEDICAL OFFICER FOR OBSTETRICS.

Applications are invited from qualified Medical Men or Women for the post of ASSISTANT MEDICAL OFFICER FOR OBSTETRICS. Candidates must have had practical hospital experience in Gynaecology and Obstetrics, and of ante-natal and post-natal clinics.

The appointment will be for twelve months, and the salary will be £300 per annum, with board, residence and laundry valued at £140. The successful candidate will have quarters at Mayday Hospital, Thornton Heath.

The Officer appointed will be on the staff of the Medical Officer of Health, and work under his administrative supervision.

Application forms may be obtained from the Medical Officer of Health, Town Hall, Croydon, on receipt of a stamped, addressed foolscap envelope, and should be returned to him not later than 11 a.m. on Monday, July 19th, 1937, together with copies of three testimonials of recent date. Canvassing in any form is prohibited.

Town Hall, Croydon. JOHN M. NEWNHAM, Town Clerk. June 23rd, 1937.

DEVON COUNTY COUNCIL (Medical Department).

Applications are invited from duly qualified medical practitioners for the appointment of ASSISTANT COUNTY MEDICAL OFFICER.

The salary, which is in accordance with the Askwith Scale, will be £500, rising by annual increments of £25 to £700.

The appointment will be subject to three months' notice on either side.

The person appointed must have special post-graduate experience in refraction work.

The successful candidate must provide a motor car for his work. Travelling and subsistence allowance will be paid in accordance with the Devon County Council Scale.

The successful candidate will be required to pass a medical examination and will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

Forms of application and conditions of appointment may be obtained from the undersigned, to whom they should be returned completed by July 17th, 1937, together with copies of not more than three recent testimonials.

4, Barnfield Crescent, Exeter. L. MEREDITH DAVIES, County Medical Officer.

The Officer appointed will be required to act as Assistant Tuberculosis Officer and School Medical Officer, and to undertake Maternity and Child Welfare Work, and such other duties as may be assigned to him.

The salary will be £500 per annum, rising by annual increments of £25 to £700, together with travelling allowance in accordance with the County Scale. Approved previous experience will be taken into consideration.

The appointment, which will be terminable by three months' notice on either side, will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass the necessary medical examination.

Applications should be made on forms which may be obtained from the undersigned and must reach him not later than July 23rd, 1937.

Canvassing in any form will be a disqualification.

County Offices, Sleaford, Lincs. W. T. PHIPPS. Clerk of the County Council.

MANCHESTER EAR HOSPITAL, Grosvenor Square, All Saint's.

The Board invite applications for the post of RESIDENT HOUSE SURGEON. (31 beds.) Salary £120 per annum. Candidates must be duly qualified and registered. Applications, with copies of four recent testimonials, to be forwarded to Mr. REGINALD S. MILFORD (Hon. Sec., Manchester Ear Hospital), c/o Mr. W. J. Ellam, 17, Brazennose Street, Manchester, 2.

VICTORIA HOSPITAL, LOVEDALE, Cape Province, South Africa.

Applications are invited for the following posts: MEDICAL SUPERINTENDENT and CHIEF MEDICAL OFFICER, TWO ASSISTANT MEDICAL OFFICERS, one of whom might be a woman.

The Assistant Medical Officers will have the entire responsibility for the patients in their wards—there are no visiting physicians or surgeons—and one of them must be prepared to undertake operative work. In addition to their special responsibilities, they will be required to take part in the general routine work of the hospital, including out-patients.

The Victoria Hospital is a part of the Lovedale Mission of the Church of Scotland. It is government-aided and is under the control of a Board constituted by the Cape Hospitals Ordinance, No. 5 of 1912.

Medical Officers must be in full sympathy with the missionary aims of the hospital, and will be expected to have or acquire as soon as possible a working knowledge of the Xhosa language spoken by patients.

The hospital is for Natives only and contains 175 beds. It is primarily a general hospital with medical and surgical wards, but has also a maternity section, a V.D. ward for women, a large department for surgical tuberculosis in children, and an out-patient department.

The Victoria Hospital prepares Native nurses for the Medical Council's examination, and is co-operating with the South African Native College, Fort Hare, in the training of Native Medical Aids for service under the Union Government. Medical officers will be required to give systematic and clinical tuition to these students. They will be members of the Medical Committee of the College.

Medical officers will receive salaries on the scale £350 rising by increments of £20 to £650. (£325-£15-£500 in the case of women.) The salaries are inclusive and are subject to pension deductions. The initial position of Medical officers on the scale will depend upon their professional standing and experience and the responsibilities assigned to them.

Medical Officers will not be allowed private practice except as consultants.

Applications should be forwarded to the Hon. Secretary of the Victoria Hospital, Lovedale, Cape Province, South Africa, so as to arrive not later than the first week of September, and should state age, professional qualifications, and experience, whether married or single, and be accompanied by testimonials

Lovedale, South Africa, June 21st, 1937. D. A. HUNTER, Hon Secretary, Lovedale Hospital Board.

The appointed candidate will work under the direction of the Medical Superintendent. The duties are mainly medical and candidates should have had medical experience, and preference will be given to candidates possessing a higher medical qualification.

Salary at the rate of £450 per annum, rising by annual increments of £50 to £550, with full residential emoluments.

The appointment will be held during the pleasure of the Council and will be subject to:

(1) The candidate passing a medical examination.
(2) To the provisions of the Local Government and Other Officers' Superannuation Act.
(3) Six weeks' notice on either side.

The officer will be required to refund to the Council all fees, allowances and emoluments other than the foregoing received by him.

Further particulars of the post may be obtained from the Medical Superintendent, City Hospital, Plymouth. Forms of application may be obtained from the undersigned, and should be returned, accompanied by copies of not more than three recent testimonials, not later than Monday, July 26th, 1937.

T. PEIRSON,
Medical Officer of Health.

Town Hall,
Stonehouse,
Plymouth.
July, 1937.

HORNSEY EDUCATION COMMITTEE.

APPOINTMENT OF AURAL SURGEON.

The Committee require the services of a part-time surgeon to attend at the School Clinic, Crouch End, on approximately 40 Saturday mornings during the year, for the diagnosis and treatment of conditions of the ear, nose and throat in children from infancy to school-leaving age. Candidates should have considerable experience of ionization and diastolisation, but the work does not include operations for the removal of enlarged tonsils and adenoids.

The fee paid for each session of two hours will be £2 12s. 6d.

Applications for this appointment, giving particulars of qualifications, etc., should be sent to the undersigned not later than Saturday, July 17th, 1937.

E. R. STOW,
Deputy Director of Education.

Education Department,
Town Hall,
Crouch End, N.8.

COUNTY BOROUGH OF TYNEMOUTH.

PUBLIC ASSISTANCE COMMITTEE.

Preston Hospital, North Shields.

SENIOR ASSISTANT MEDICAL OFFICER. (Male, Non-Resident.)

The Council of the County Borough of Tynemouth invites application from registered male Medical Practitioners for the appointment of Senior Assistant Medical Officer (Non-Resident) at the above-named Hospital.

The salary will be at the rate of £450 per annum, rising by annual increments of £25 to £550 per annum; the officer appointed will be required to refund to the Council all fees received by him.

The appointment will be subject to one month's notice on either side, and the officer appointed will be required to submit a satisfactory medical certificate, to devote the whole of his time to his official duties, and to act under the direction of the Medical Officer.

Candidates should have had experience as Medical Officers resident in a general hospital, and preference will be given to candidates who have also had similar experience in a maternity hospital. The selected candidate will be required to commence duties on September 1st, 1937.

Applications, stating age, experience, and qualifications, and accompanied by not more than three recent testimonials, should be forwarded to the undersigned not later than July 20th, 1937.

Canvassing, either directly or indirectly, will be a disqualification.

Dated the 9th day of July, 1937.

FRED G. EGNER,
Town Clerk.

14, Northumberland Square,
North Shields.

SOUTHEND-ON-SEA GENERAL HOSPITAL. (235 Beds.)

Applications are invited for the post of FIRST HOUSE SURGEON, duties to commence on August 1st. Appointment is for six months. Salary £100 per annum with Board, Residence and Laundry. Candidates must be registered (Male) Practitioners. Applications with copies of two recent testimonials to be sent to the undersigned by July 15th, 1937.

P. H. CONSTABLE,
Secretary.

Applications for either of the above posts should be forwarded to the undersigned immediately, together with copies of three recent testimonials, stating age, qualifications, experience, etc.

By Order of the Board,
HERBERT J. DAFFORNE,
General Superintendent and Secretary.

BURY INFIRMARY (LANCS.). (127 Beds.)

APPOINTMENT OF CASUALTY OFFICER (MALE)

A vacancy as above arises on the Resident Medical Staff, and applications are invited for the post.

The Resident Staff consists of an R.S.O., a House Surgeon, and House Physician, and a Casualty Officer.

In addition to his duties in the Casualty Department the Casualty Officer is also responsible for the In-patient and Out-patient work in connection with the Eye, and Ear, Nose and Throat Department.

The appointment is for six months at a salary at the rate of £150 per annum, with board, residence and laundry, and the successful candidate will be expected to commence duties immediately.

Applications, stating age, qualifications, and nationality, together with copies of three recent testimonials, are to be forwarded to the undersigned as soon as possible, endorsed "Casualty Officer."

Further particulars may be had on application.

H. WILKINSON,
Superintendent.

ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

Applications are invited for the following posts:
(a) HOUSE PHYSICIAN from August 1st.
(b) HOUSE SURGEON from August 1st.

Each appointment is tenable for a period of six months, but is terminable at an earlier date by one month's written notice on either side.

The salary of each officer will be at the rate of £130 per annum, with board, residence and laundry.

Candidates (male), who must be unmarried and duly registered, are requested to forward their applications, stating age, qualifications, etc., together with copies of not more than four testimonials, to the undersigned on or before Wednesday, July 14th, 1937.

J. A. BEARDSALL,
Secretary-Superintendent.

ST. MARY'S HOSPITALS, MANCHESTER.

ASSISTANT RESIDENT OBSTETRIC OFFICER for the Whitworth Street West Hospital (Maternity) for a period of twelve months from August 1st next. Salary £100 per annum, with board and residence. Membership of the College of Obstetricians and Gynaecologists would be an advantage. Applications, with copies of three testimonials, to be sent to the undersigned on or before the 12th instant.

R. RATCLIFFE, Secretary.

ROYAL EYE & EAR HOSPITAL, BRADFORD. (94 Beds.)

HOUSE SURGEONS (two) required. Salary £150, with board, residence and laundry.

Applications, stating qualifications, age, etc., with copies of recent testimonials, should be sent to the undersigned.

F. BRIGGS,
Secretary-Superintendent.

Manager:—W. M. SCOBIE.

The Offices are situated at 21, ALVA STREET, Edinburgh, being quite close to the West End of Princes Street, and within two minutes' walk from the offices of the British Medical Association and Medical Insurance Agency Ltd., at 7, Drumsheugh Gardens.

Terms on which the business of the Branch is transacted will be submitted on application to the Branch Manager, to whom all communications should be addressed.

BOVRIL MEDICAL AGENCY, LTD.

ALDINE HOUSE,

10-13, BEDFORD STREET, STRAND, LONDON, W.C.2.

Telegrams: BOVMEDICAL, LESQUARE, LONDON. **Telephone: TEMPLE BAR 1616 (3 Lines).**

Chairman and Managing Director, Dr. J. FIELD HALL.

The maximum commission payable on the sale of any Practice or Partnership in Great Britain placed exclusively in the hands of this Agency is £50 (fifty pounds), which sum covers goodwill, drugs, surgery fittings, fixtures and furniture, instruments and book debts, but not house property. Schedule of Terms will be forwarded on application.

Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.
No charge is made to Principals for the introduction of Locum Tenens or Assistants.

1. SURGICAL OPENING.—Beautiful country within 50 miles of London.—A share to produce £1,000 p.a. is offered to a Fifth Partner in a high-class old-established PRACTICE. The patients comprise all classes and there is little visiting done under 10/6. Ingoing partner, who would do all the surgery for the firm, must also be prepared to do general practice. There would be a hospital appointment after 12 months. Choice of residences. Applicants must be aged 28-40, preferably have a University degree and must hold the English Fellowship. Premium 2 years' purchase.
2. NORTH LONDON.—PRACTICE producing £758 p.a., including £322 from Panel and £135 from one appointment. Fees 2/6 to 3/6. Visits 3/6 to 5/-. Suitable accommodation available, 2 consulting rooms, waiting room and dispensary with separate entrance—2 reception rooms, 7 bedrooms. Nett outgoings approximately £107 p.a. Premium £1,250.
3. HOLIDAY RESORT ON THE EAST COAST.—ASSISTANTSHIP with view to PARTNERSHIP after six months in an old-established general mixed Practice, the gross receipts of which are about £6,500. Panel of 3,000 patients and appointments produce about £550 p.a. A share to give about £1,000 p.a. will be offered to a suitable applicant who should be capable of undertaking major surgery and be accustomed to good class work.
4. LONDON, S.W.—Old-established PRACTICE available as house is too small for Vendor's family. Held by previous Vendor for some 30 years. Receipts are stated to be £1,500 p.a. Panel of 1,266 patients. One appointment producing £60 p.a. and small club which brings in about £25 p.a. Fees 2/6. Visits 3/6 and 5/-, all inclusive of medicine. House available contains surgery, waiting room and dispensary, 2 reception and 2 bedrooms, bathrooms, etc. For sale at £1,200 or might be rented. Premium £3,000.
5. KENT.—Old-established Country PRACTICE for sale, held by Vendor for past 9 years and only available because of ill-health. Gross cash receipts for year ended 30/6/37, stated to be £1,477. Panel of 650 patients, producing £390 p.a., and several small appointments which bring in about £70 p.a. Nearest opposition 2½ miles away. Fees 3/6 to 7/6. Visits 3/6 to 15/- with a few at 21/-. Very little midwifery. Beautiful house—freehold for sale for £2,400. It contains consulting rooms and waiting room, 2 reception, 5 bedrooms, garage for 3 cars, good garden with tennis lawn, rockery and orchard. Main water and electric light. All kinds of sport and good educational facilities. Premium £2,600.
6. LONDON.—WEST END.—A THIRD PARTNER is required in an old-established good-class, steadily increasing Practice averaging £7,000 p.a. Share offered to produce guaranteed income of £1,000 p.a. Minimum fee 10/6. Ingoing partner should be about 30 to 33, married, hold a University degree and be used to high-class Practice.
7. NORTH-WEST COAST.—SEASIDE TOWN.—CONSULTING PRACTICE FOR A PHYSICIAN.—Established by vendor (who now wishes to come to London) 4 years ago. Receipts for last year stated to be £1,320. Minimum fee 2 gns. Suitable rooms available at inclusive rental of £64 p.a. Purchaser can choose his own residence and should hold the M.D. or M.R.C.P. Premium 1½ years' purchase on actual receipts for first year.
8. HAMPSHIRE.—COUNTRY PRACTICE.—Old-established PRACTICE held by vendor for past 7 years. Gross cash receipts stated to average £740 p.a. Panel of 472. Appointments worth about £130 p.a. Fees 3/6 upwards. Pleasant house containing 2 reception, 5 bedrooms, etc., Professional accommodation. Good garden and garage. Rent £55 p.a. Premium £1,250.
9. SUSSEX.—PARTNERSHIP.—A ONE-FIFTH SHARE (producing approximately £840 p.a.) is for disposal in a particularly sound good mixed class Practice situated in beautiful country and residential district within easy reach of sea. Fees from 3/6. Suitable house with 2 sitting, 6 bedrooms, separate professional rooms. Half an acre of garden, garage for two cars. Sport of all kinds and good schools within reach. Ingoing partner should be married, a graduate, and aged between 30 and 35.
10. NORTH-WEST COAST.—SUBURB OF FAVOURITE SEASIDE RESORT.—Well-established middle-class PRACTICE, steadily increasing, with good scope for further development. Gross cash receipts for immediate past 12 months £1,458, including Panel of about 400. Visits 5/- upwards, medicine extra. Very nice house with ample accommodation and garden can be rented at £104 p.a. Good sport and excellent educational facilities. Premium £2,004. Vendor retiring.
11. LONDON, SOUTH-EAST.—Middle-class PRACTICE held by vendor nearly 30 years, averaging over £700 p.a. Panel of 576 and one appointment worth £25 p.a. Roomy house with good garden and garage. Leasehold for sale.
12. OUTLYING NORTHERN DISTRICT.—Old-established non-Panel good mixed-class PRACTICE held by vendor (who is retiring) many years. Average gross cash receipts approximately £1,400. Fees 3/6 to 15/-. Good house with 2 reception, 7 bedrooms, etc., garden, garage. On rental. Premium 2 years' purchase.
13. DEATH VACANCY.—CUMBERLAND.—Unopposed, old-established PRACTICE situated in beautiful country district near sea and held by late incumbent 30 years. Gross cash receipts average about £1,000 p.a., including Panel worth over £250 p.a., and appointments worth nearly £80 p.a. Suitable 8-roomed house with bathroom, surgery, dispensary, etc., garden, garage. Rent £40 p.a. Shooting, fishing, golf, etc. Premium 1 year's purchase.
14. OUTLYING EASTERN SUBURB.—Sound PRACTICE established over 40 years and averaging approximately £1,700 p.a., including Panel of about 2,200 patients. Suitable accommodation can be rented at 30/- per week. Premium £4,000.
15. SUSSEX.—VILLAGE PRACTICE NEAR COAST.—Well-established Practice, producing about £800 p.a., and capable of increase, attractively situated within five miles of favourite seaside resort. Very nice house, with ¾ acre of garden, in excellent repair. Price for Practice and house, £3,100 or house might be rented for a short period.
16. LONDON.—WESTERN DISTRICT.—Old-established Private PRACTICE for disposal after being held for many years by the Vendor who is retiring. Approximate cash receipts for the last year amount to £1,062. There is stated to be scope for increase, particularly if Panel work is undertaken and also midwifery. Fees 3/6 to 10/6. Small compact house available on rental at £90 p.a., containing consulting room, 2 reception rooms, 3 bedrooms, etc. Premium £1,800.
17. ESSEX.—Death Vacancy.—Old-established PRACTICE for disposal. It has been held by the Vendor for the past twelve years. The gross cash receipts for the last year were approximately £756. Panel of 424 patients. Fees 2/6 and 3/6 with a few midwifery cases at 3 guineas. Suitable house for disposal, containing 2 reception rooms, 3 bedrooms, etc.
18. DEATH VACANCY.—FAVOURITE SOUTH-COAST TOWN.—Old-established PRACTICE producing £800 p.a., of which about £600 is derived from a Panel of 1,200 patients, and an appointment producing about £30 p.a. House with 3 reception, 4 bedrooms, etc., to be rented on lease. Premium £1,500 to include household fittings and fixtures.
19. SOUTH-COAST SEAPORT.—Long-established PRACTICE for disposal owing to Vendor's retirement. He has held it for the past 39 years. Income last year approximately £573 with a Panel of about 460 patients. Vendor previously held a public appointment producing £450 p.a., which he relinquished owing to age limit. It is considered that anyone devoting whole time to the Practice would increase the receipts. Suitable accommodation available on rental.
20. EASTERN COUNTIES.—Mixed-class PRACTICE in pleasant agricultural district producing for last 12 months over £1,300 p.a. Fees 3/6 to 21/-. Nice house in good position with 2 reception, 4 bedrooms, dressing room, etc. Separate professional accommodation. Modern conveniences. Garden, garage. Price for freehold £1,300. Sport of all kinds and schools within reach.
21. EAST ANGLIA.—WITHIN REACH OF TWO GOOD TOWNS.—Old-established, unopposed country PRACTICE averaging over £1,000 p.a., including Panel producing over £450 a year. Low expenses. Detached house in own grounds, containing 2 sitting rooms, 5 bedrooms, etc. Rent £70 a year. Premium £1,750.
22. LONDON.—NORTH-WEST.—Recently established and steadily developing PRACTICE producing for last 12 months approximately £1,000, and increasing at the rate of about £200 p.a. Suitable house can be rented or flat obtainable. Premium 2 years' purchase.
23. LONDON.—SOUTH-WEST (CROYDON AREA).—Old-established good middle-class PRACTICE producing for last 12 months £1,576 p.a., including Panel of about 1,300. Suitable house with 2 reception, 5 bedrooms, etc., can be rented at £80 p.a. Premium 1½ years' purchase. Illness reason for sale.
24. EASTERN COUNTIES.—Very sound unopposed middle and working-class PRACTICE in agricultural district averaging £1,150 p.a., including Panel worth about £460 p.a. Fees from 3/-. Nice house with 2 reception, 6 bedrooms, etc., electric light, garden, garage. Premium for Practice and house, £3,350.
25. NORTHERN SUBURB WITHIN 10 MILES OF HYDE PARK.—Recently established better-class PRACTICE, steadily increasing and producing for last 12 months £760. Panel of about 560 and appointments worth £40 p.a. Good freehold house with 4 bedrooms, etc., garden, garage. Price £1,450. Premium £1,450 or near offer. Vendor retiring.
26. EASTERN COUNTIES.—COUNTY TOWN.—Well-established PRACTICE averaging about £1,100 p.a., including Panel of 1,061 and clubs producing about £350 to £400 p.a. Vendor retiring through ill-health and age, and states there is excellent scope for increase.
27. NORTH-EAST COAST.—Old-established PRACTICE producing about £900 p.a., but stated to be capable of considerable increase. Choice of houses Partnership introduction given, as vendor retiring.
28. MIDLANDS.—FAVOURITE RESIDENTIAL TOWN.—Chiefly better class non-dispensing PRACTICE, producing for last 12 months over £1,600. Panel of 560 and one appointment worth £150 p.a. Fees 3/6 to 21/-. Very nice house with ample accommodation, garden and garage. Freehold for sale. Premium 2 years' purchase.
29. CENTRAL LONDON.—PRACTICE is worked as a "Lock-up" and averages about £1,000 p.a. Fees from 2/6. Suitable accommodation can be obtained. Premium 2 years' purchase.
30. CROYDON AREA.—Recently established PRACTICE. Receipts for last 12 months over £660, including Panel of 350. House with 3 bedrooms, etc., garden and garage can be rented at £85 p.a. Premium £750.
31. SUSSEX.—ATTRACTIVE DISTRICT NEAR SEA.—PARTNERSHIP.—A ONE-FOURTH SHARE is offered (after preliminary assistantship of 6 to 12 months) in old-established Practice having good scope. Gross cash receipts for last 12 months approximately £3,275. Panel of about 1,300. Appointments worth over £300. Choice of houses on rental for ingoing partner. Premium 2 years' purchase.
32. NORTH LONDON.—Old-established PRACTICE producing about £700 p.a., including Panel of nearly 600 patients. Suitable house, ample accommodation and good garden, garage, to rent at £100 p.a. Premium £1,200.
33. SUSSEX COAST TOWN.—PRACTICE established 45 years for disposal owing to retirement of Vendor. Present receipts about £600. There is stated to be scope for increase as receipts have fallen owing to Vendor's illness. Panel about 650. Large house can be rented at £150, or purchaser could probably choose own residence.
34. LONDON.—SOUTH-EAST.—Old-established PRACTICE producing about £1,830 p.a., including select panel of 500. Fees from 3/6. Suitable house available with 2 reception, 5 bedrooms, etc. Freehold for sale. Premium 2 years' purchase.

WANTED TO PURCHASE.—PRACTICE OR PARTNERSHIP producing £500 p.a. upwards, and situated within 2 miles of Highgate.

The Agency has made arrangements for special facilities, on very favourable terms, to be afforded to approved purchasers for the advance of part of the premium for any suitable practice or partnership. Full details on application.

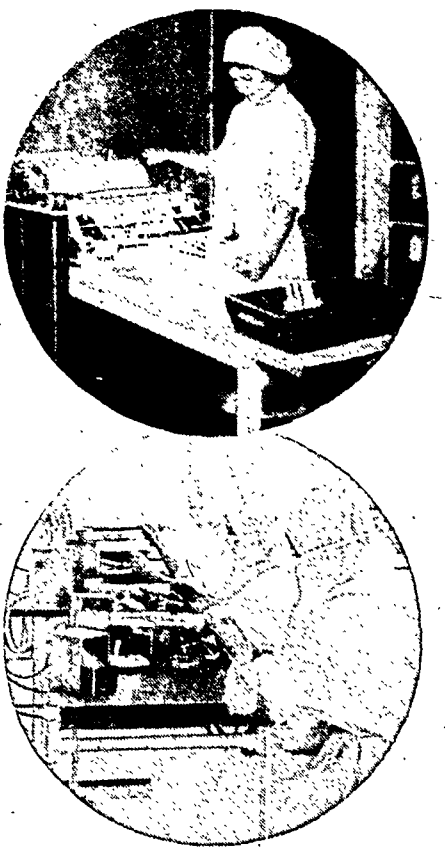
Heat Sterilized without loss of flexibility

Surgical Catgut is manufactured from the submucous cellular coat of the sheep's intestine.



This material is converted into gelatin by the action of heat in the presence of moisture.

Heat sterilization is carried out therefore, after complete dehydration of the catgut. After sterilization, the tubes of catgut are filled with a 96% alcoholic solution, the 4% aqueous content imparting flexibility to the suture.

This variety of catgut, as taken from the tube, has the correct degree of flexibility and tensile strength. The suture requires no conditioning before use.

The entire product manufactured *in England.*

Descriptive booklet will be sent on application.

TOP—Removal of the mucous coat by mechanical means, before decomposition commences.
BOTTOM—Hermetically sealing glass tubes containing sterile catgut.

The Most Successful

VOLUME I VOLUME II

VOLUME III

EDITED BY CECIL P. G. WAKELEY

"MODERN TREATMENT IN GENERAL PRACTICE"

"Empire-wide approval."

ENGLAND says: "A very serviceable and particularly useful presentation of modern methods and their application in general practice."—*British Medical Journal.*

"Illuminating and helpful; the names of the authors suffice to give assurance that the articles are authoritative and that the treatment is customary and based on present-day conceptions of disease."
—*West London Medical Journal.*

INDIA says: "This book should be in the library of every medical practitioner in this country."
—*Indian Medical Gazette.*

"A wide and valuable survey of the latest advances in medicine and surgery . . . a sure and certain guide."
—*Indian Medical Journal.*

AUSTRALIA says: "This is a useful volume covering a wide range of subjects . . . it will appeal to the general practitioner. Volume I was successful and had to be reprinted; a similar fate, we think, awaits Volume II."
—*Medical Journal of Australia.*

NEW ZEALAND says: "A real help to practitioners who try to keep abreast of modern methods of treatment; can be heartily recommended."—*New Zealand Medical Journal.*

CANADA says: "We find the second volume even more valuable to the general practitioner than the first . . . of great value and an excellent post-graduate course."
—*Canadian Medical Journal.*

Books for Many Years!

An Opinion

"The Medical Press & Circular" is in many ways the ideal journal for the medical practitioner. The Editor started the series of articles "Modern Treatment in General Practice," these have been deservedly popular and their reissue in book form year by year is a very welcome step. Everyone can afford the price of these books and everyone should read them."

MODERN TREATMENT IN GENERAL PRACTICE.

VOLUME I. Third Reprint ready.

VOLUME II. Large edition nearly exhausted.

VOLUME III. Just Published.

SUBSCRIPTION to Medical Press. Order To-day.

   (1) "Gases used in Chemical Warfare."
   (2) "Public Health Services."
   (3) "Declining Fertility."
5. **"Quarterly Symposiums."** (24-pp. Supplements) on:
   (a) "Ante-natal Treatment."
   (b) "Athletic Injuries."
   (c) "The Eye."
6. **"Special Numbers"** on:
   (a) "Milk."
   (b) "Dietetics."

The *Medical Press and Circular* is "the most useful paper a man in general practice could have."
(A G.P.'s opinion)

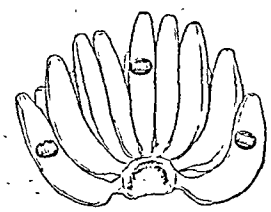
These 5 layers give you the full flavour and no bits in the mouth

There is a good reason for the wide recommendation of "du Maurier" cigarettes by the medical profession. The filter tip ensures no bits in the mouth. Three layers of pure white vegetable tissue interleaved by two layers of cellulose fibre keep every hint of irritation from a sensitive throat. And "du Maurier" are made with both plain and cork tips.

du MAURIER

the perfect cigarette with the exclusive filter tip

TEN FOR SIXPENCE • TWENTY FOR ONE SHILLING



THE THERAPEUTIC VALUE OF THE BANANA

1. The Enzymes The banana is comparatively rich in enzymes, amylase, sucrase, a protease and a lipase being present.

Of these, perhaps the protease is of the greatest value to the convalescent, owing to its faculty of splitting up protein into the simpler soluble nitrogenous bodies (amino-acids) necessary to tissue-building.

Protease is also notable for breaking down the casein of milk, forming tryptophane, the most important amino-acid of them all.

It is for this reason that so many medical men are prescribing a mash of milk and bananas for convalescents and young children, especially in cases of coeliac disease.

N.B. In the fully ripe banana the starch content is reduced to about 3 per cent, having been changed into soluble sugars. A banana is ripe when all green has disappeared from the skin and brown spots have formed upon the yellow surface.

The advantages of the Curtis Abdominal Support No. 1 lie in its anterior - posterior pressure. By this method the lower abdomen is effectively supported while the hips are given complete freedom of movement. This, combined with its scientific design and extreme lightness in weight, makes the Curtis Abdominal Support No. 1 the most efficient and comfortable on the market.

INFANTILE ECZEMA.

A quick cure—'would usually take months' writes doctor.

The doctor's letter:

". . . I happened to have in my consulting room a baby with eczema of the scalp, which would normally have taken me months to cure.

I tried it with Sphagnol Ointment with most satisfactory results, and am so pleased with the preparation that I should be grateful if you would forward me a pound package of it."

Yours truly,
———, M.B.

Reports of speedy cures with Sphagnol Ointment are not uncommon, but the great virtue of Sphagnol Ointment is this—that from the first touch it is soothing, cooling. Used against eczema, Sphagnol brings sure relief from itching, and at the same time its healing peat principle helps the growth of clear, healthy skin.

Perhaps you have had no personal experience of Sphagnol. Then the makers will gladly send you free samples.

Sphagnol

Peat Products (Sphagnol) Ltd., Dept. B. 211, 21, Bush Lane, London, E.C.4.

SOMNIGEN

The advantage of "Somnigen" is that it does not produce the Headache, Nausea, Furred Tongue, or Constipation so frequently noticed when preparations of Opium or Morphine are administered. It contains the whole of the Alkaloids of Opium in chemical combination with Hydrobromic Acid, which assists the sedative action, and is STANDARDISED so as to contain 0.75 per cent. Morphine, but entirely free from nauseous odour and characteristic taste.

As an Hypnotic, Sedative, Opiate and Diaphoretic it has always given great satisfaction, as its action is most regular and certain, producing refreshing sleep without unpleasant after-effects

"It is free from the odour of the ordinary Tincture of Opium, and does not produce the same disagreeable after-effects."
—THE MEDICAL ANNUAL.

"It has the advantage of not being followed by nausea and headache and other drawbacks of Laudanum."
—THE INDIAN MEDICAL GAZETTE.

THE DOSE IS 5 TO 40 MINIMS.

Packed in 5-oz., 10-oz., 22-oz., 40-oz., and 90-oz. Bottles.

INTRODUCED AND PREPARED ONLY BY

C. J. HEWLETT & SON, Ltd., 35 to 42, CHARLOTTE STREET, LONDON, E.C.2.

NEO-MONSOL GERMICIDE

FOR SAFE ANTISEPSIS:

Six times stronger than pure Carbolic Acid.

Have You investigated

Vita Pure Vineyard Grape Juice retains the therapeutic power of the living fruit, because its ferments are alive and vigorous. During the past months hundreds of practitioners have investigated this statement and found Vita worthy of their recommendation for nutritional maladies and as a 'health-giving' early morning drink. Concentrated by a low temperature process which keeps the vitamins unchanged, Vita is non-alcoholic and economical. A tablespoonful well diluted with water is a recommended dose.

VITA GRAPE JUICE

We invite the practitioner to enquire for further particulars and a sample bottle. Will you please investigate VITA, too?

VITA CONCENTRATED JUICES LTD.

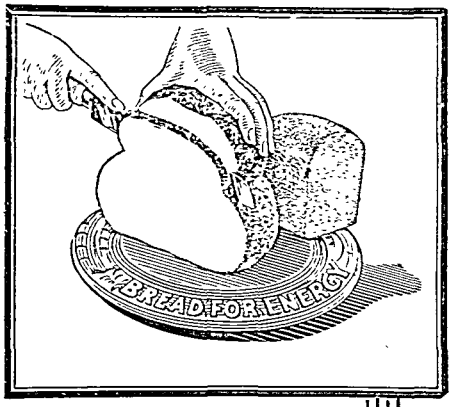
MANDELIX

(Elixir of Ammonium Mandelate B.D.H.)

In Urinary Tract Infections

Mandelix therapy possesses the following advantages:



1. The elixir is administered orally, and supplementary administration of ammonium chloride is unnecessary.
2. The flavour of Mandelix is acceptable, and the treatment has the willing co-operation of the patient.
3. Sterile urine is produced usually within a week, even in chronic infections.

NEW

In the treatment of
TRICHOMONAS VAGINALIS
and non-specific vaginitis

'PICRAGOL' *Regd.*

Insufflator
Brand Vaginal Powder
Brand Vaginal Pessaries

Excellent results have been reported both in general practice and in controlled tests carried out in a leading London clinic from a new therapy for the treatment of vaginal disorders, in particular vaginitis due to Trichomonas Vaginalis infestation. This therapy consists of two insufflations at one week's interval using the special 'Picragol' insufflator (illustrated above) and 'Picragol' vaginal powder. Following each insufflation one 'Picragol' pessary is inserted each night for six nights. A large percentage of cures has been established at the end of a fortnight's course of treatment as outlined above.

Physicians who are interested in this new therapy are invited to write for details to

JOHN WYETH & BROTHER LTD., 25, Oldhill Place, London, N. 16

Modern Iron Therapy

Iron 'Jelloids' are an elegant and reliable means of administering the proto-carbonate of iron. The preparation has none of the disadvantages of Pil. Blaud. The iron content remains fresh and unoxidized indefinitely, and injury to the teeth is avoided.

The 'Jelloids' are highly effective in the treatment of achlorhydric anæmia and indeed in all the simple anæmias in which massive iron therapy is indicated.

Iron Jelloids

You are cordially invited to apply for samples for clinical test.

Hyperpepsia—*Intermittent hyperchlorhydria.*
Hypopepsia and apepsia—Dyspepsia arising from disturbance of neuromotility.
Intermittent pyloric stenosis, not of organic origin.

SECONDARY DYSPEPSIAS:
Arthritic dyspepsia.
Toxic dyspepsia (gastro-hepatic).
Dyspepsia due to enteroptosis.

MALARIA AND TROPICAL DISEASES. URINARY GRAVEL.

NATURAL VICHY SALT for Drinking and Baths.

INDICATIONS.

HEPATIC.

Congestion due to excessive or improper feeding.
Congestion due to cirrhosis (before the cachectic stage).
The diathetic congestions of diabetic, gouty, and obese persons.
Congestion due to poisoning (mercury, morphine, etc.).
Toxic congestion (influenza, typhoid fever, etc.).
Biliary lithiasis.

DIATHESIS.

The diabetes of fat people. Arthritic obesity. Uricaemia and gout. Rheumatic gout.

VICHY DIGESTIVE PASTILLES prepared with Natural Vichy Salt.

CAUTION.—Each bottle from the STATE SPRINGS bears a neck label with the word "VICHY-ETAT" and the name of the SOLE AGENTS

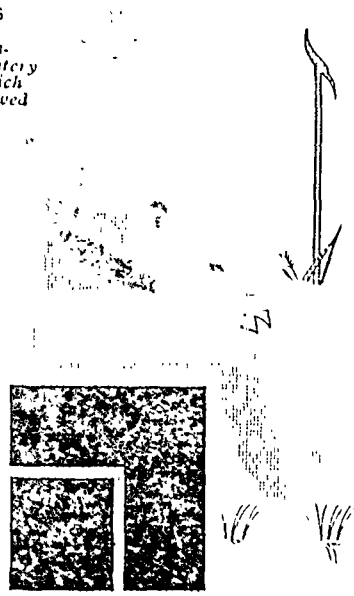
COLLIRON

(*Evans*)

In the Anaemia of Pregnancy

Much fatigue during pregnancy is due to anaemia and this adds to the hazard of other complication which may occur. The accepted treatment is inorganic iron in ample dosage, but as many anaemias accompany a long-standing deficiency of gastric acidity, the iron should be in a form which is readily available to the system.

Colliron is ideal for this purpose as it is readily assimilated being a concentrated colloidal solution of Ferric Hydroxide. A graded course will often prove beneficial also in the last three months of normal pregnancies.



Dosage:—20 minims three times daily

Colliron is issued in bottles:
4-fld. oz., 3/- ; 8-fld. oz., 5/- ; 16-fld. oz., 9/6 ; 80-fld. oz., 40/- (Hospital size)

OVALTINE

IN SICKNESS AND CONVALESCENCE

GODDESS NEITH. *Personification of watery Abyss which was endowed with self creation.*

THE impairment of digestive powers which is commonly met with in the feverish patient, combined with the lack of desire for food, often aggravates the difficulty of adequately replacing the increased loss of energy and destruction of tissue which occur.

"Ovaltine" provides a satisfactory solution to the problem of alimentation in many cases of sickness and in the stage of convalescence after severe, prolonged and debilitating illnesses, where an easily assimilable, palatable and concentrated nutrient is required. It is always acceptable.

"Ovaltine" replaces with advantage the ordinary milk preparations which so often prove distasteful to the invalid. Prepared from full-cream milk, eggs and malt extract in carefully balanced proportions, it provides complete nourishment in the most readily assimilable form.

A liberal supply for clinical trial sent free on request.

UNYIELDING SKIN LESION

(Psoriasis—Duration 21 years)

which did not respond to previous treatment

PERMANENTLY ELIMINATED

with

BELZEMA

BRAND OINTMENT

The case illustrated had resisted treatment for 21 years. Lotions, ointments, violet ray and mineral baths were employed ineffectively. BELZEMA soap and BELZEMA OINTMENT completely eliminated the condition in less than four months. This says more for the action of the BELZEMA Treatment than could easily be expressed in words. It has long been proved valuable in a wide range of indications :

ECZEMA • **ACNE**
PSORIASIS • **DANDRUFF**
RINGWORM • **ALOPECIA**

and other skin disorders.

BELZEMA **SOAP**

cleanses and prepares the skin for the absorption of BELZEMA Ointment. It is absolutely pure—contains no synthetic perfume — no artificial colouring—no free alkali — recommended for personal hygiene.

PHOTOGRAPHED NOVEMBER 4, 1932.

NOT A SMEAR — There is no greasy residue. It is completely and rapidly absorbed.

NO BANDAGING — Permits air to act freely. Allays itching at once.

ECONOMICAL — Permanency of results establishes BELZEMA Ointment as an effective and economical treatment.

EVERY PHYSICIAN SHOULD TEST THE BELZEMA TREATMENT. Send for samples for clinical trial to :—

IODATOL, 40 PER CENT.

For use in X-Ray Diagnosis

Iodatol, 40 per cent., a pale, viscous oily fluid, opaque to X-rays, conforms with the official specification for iodised oil—Oleum Iodisatum (Addendum 1936 to the *B.P.* 1932).

The injection of Iodatol, 40 per cent., as a means of conducting explorations of various delicate organs and cavities of the body, is regarded as a routine procedure. In bronchiectasis it makes possible a complete investigation of the bronchial tree; in spinal disease it renders possible the diagnosis of spinal cord tumour. It is employed in salpingography, in suspected pulmonary tumours and in the exploration of abscesses and fistulae.

Iodatol also finds a useful place in therapeutics.

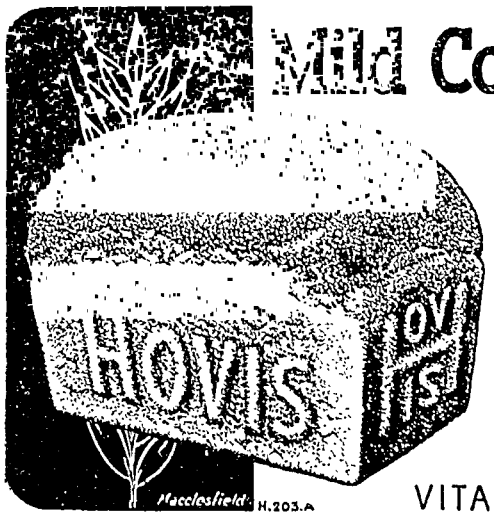
For the patient who is run-down or depressed

In the case of the patient who for no apparent reason is run-down or depressed and, generally, 'below par', a course of Livogen often brings about spectacular results.

The appetite returns, metabolic processes are stimulated, depression disappears, and a return to the 'joy of living' is apparent.



Livogen is rendered particularly acceptable at this season of the year if it is administered in iced water or soda water.

Mild Constipation shown to yield to laxative effect of HOVIS

Many of the mild forms of constipation so prevalent to-day are attributed to the consumption of foods deficient in Vitamin 'B.' In comparing the effects of various kinds of bread it is seen that HOVIS germ bread is superior to either white bread or wholemeal in supplying this deficiency.

Whilst white bread contains practically no Vitamin 'B,' HOVIS, with its added proportion of 25% wheat-germ, supplies an abundance of this essential food-element. Unlike wholemeal bread, HOVIS contains only a minute percentage of bran and indigestible cellulose. In other words its incorporation in the normal diet ensures not only a higher standard of nutrition but easier assimilation and regular evacuation of the intestinal contents.

Cystopurin

The ideal urinary antiseptic for oral administration!

1 Produces no gastric irritation or toxic symptoms.

2 Is readily absorbed from the gut and excreted in the urine.

3 Causes no renal irritation.

4 Renders the urine bactericidal in low concentrations.

5 Acts from the renal pelvis downwards.

6 Is active in either acid or alkaline urine.

7 Perfectly safe for use in febrile conditions.

8 Acts on all causative organisms of urinary infections.

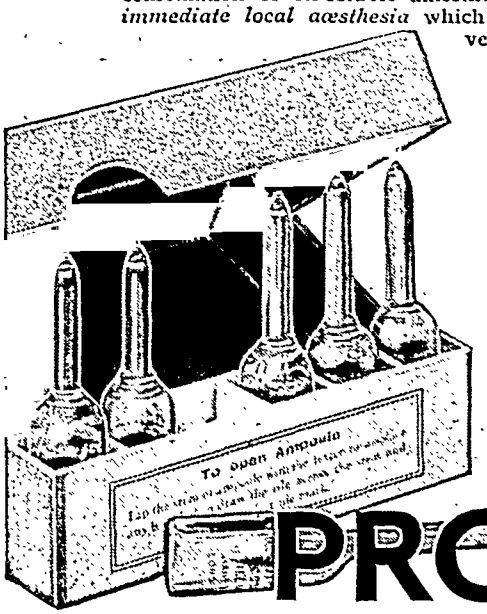
CYSTITIS

From information received :—

"About six weeks ago I came across a bad case of cystitis and sent a sample of the urine to the —— Research Labs. The reply I got from them was that in cultivation the urine showed masses of streptococci. I was very anxious to see what effect —— would have on this condition and, after three weeks of this treatment, I was doomed to disappointment, due, I suppose, to the fact that there must have been some mixed infection there. I switched over to Cystopurin, and this week I have had a letter from the —— Labs. to say that on bacteriological examination no growth of organisms could be obtained on culture. You will thus see how gratifying my experience has been with Cystopurin, and I can assure you that my patient is just as overjoyed at the result as you and I are."

"I have been treating a case of chronic cystitis of nine months' duration, the sequel to an acute attack. This case had resisted treatment by alkalies, two courses of hexamine and acid sodium phosphate and other remedies. Under treatment with Cystopurin the cystitis has now cleared up, and there has been no relapse for nearly two months."

"I have used your Cystopurin repeatedly in cases of cystitis and have found it an excellent urinary antiseptic. I find that patients have NO GASTRIC COMPLAINTS WHILE TAKING CYSTOPURIN, a thing which cannot be said of the ordinary hexamine preparations."



Supplied in bulk and in tubes of 20 tablets for dispensing purposes.

"Proctocaine" is a lasting, non-toxic, local anæsthetic, for use in irritating or painful conditions of the skin and subcutaneous tissues. It is an improved form of A.B.A. "Proctocaine" is a combination of oil-soluble anæsthetics of low toxicity. These are combined so as to produce *immediate local æsthesia* which is maintained by the slow, uniform absorption of its oily vehicle, and action of its oil-soluble ingredients.

The advantages of "Proctocaine" over other solutions have been found[1] to be as follows:

1. Its effect is almost certain.
2. It produces anæsthesia or hypo-anæsthesia for periods varying from 7 to 28 days or longer.
3. The relaxation which it produces in the anal musculature is much greater and more prolonged.
4. It is comparatively non-toxic, injection of 20 to 30 c.cm. producing no general effect.
5. Even large quantities of it at one sitting have not been found to produce any local reaction if injected properly.
6. Its injection is painless if made slowly.
7. In no case did it produce severe after-pain.

Summer Holiday Precautions . . . .

Summer holidays, desirable and enjoyable as they often are, do not always prove as health-giving as is commonly assumed. The change of surroundings, of diet, and of habits not infrequently leads to a feeling of lassitude and malaise that goes far to neutralise the benefits and pleasure of the holiday. The immediate cause of this state of subnormal health is generally an overloading of the tissues with the waste products of metabolism. Elimination of these potential poisons is promoted by taking a regular morning glass of ENO'S "Fruit Salt." This sparkling and refreshing saline has no irritant effect on the mucous lining or the nerve-endings of the stomach or intestines; its action in promoting gentle peristalsis being due to its power of retaining fluid within the alimentary canal, through osmosis.

ENO'S "Fruit Salt" is a carefully prepared combination of fruit acids and alkalis; its agreeable impression on the palate owes nothing to sugar or added flavouring. It makes a valuable addition to the contents of the travelling bag, and may safely be recommended to patients for use when away from home.

ENO'S "FRUIT SALT"

The words 'Eno' and 'Fruit Salt' are registered trade marks.

BRITISH MEDICAL JOURNAL

LONDON SATURDAY JULY 17 1937

PRONTOSIL IN THE TREATMENT OF ERYSIPELAS

A CONTROLLED SERIES OF 312 CASES*

BY

W. R. SNODGRASS, M.A., B.Sc., M.D., F.R.F.P.S.G.

Assistant Physician, Western Infirmary, Glasgow

AND

T. ANDERSON, M.B., Ch.B., M.R.C.P.Ed.

Deputy Superintendent, Ruchill Hospital, Glasgow

There is by this time a considerable literature on the experimental and clinical results of the use of prontosil and the sulphonamide derivatives. It is not intended to review that literature in this paper. It may be pointed out, however, that so far as erysipelas is concerned no work has been published dealing with a large series of cases properly controlled. There has not been comparison with other cases of the disease during the same period of review, in every way similar as regards nursing and diet and differing solely in the special lines of treatment to be investigated. Such a series is presented here.

The material consists of all cases diagnosed as erysipelas after admission to Ruchill Hospital, Glasgow, from the middle of May, 1936, to the middle of February, 1937. Erysipelas is a notifiable disease, and Ruchill Hospital receives all notified cases of erysipelas admitted to hospital in Glasgow, so that the material is thoroughly representative of the incidence of the disease in this district during the period reviewed. All the patients were under the clinical control of one of us (T. A.).

Plan of Investigation

Apart from the specific treatment shortly to be described all cases were treated under strictly comparable conditions. Thus the wards to which they were admitted and the personnel of the nursing staff were common to all groups. A standard diet was adopted. When required the same laxatives were used. No local treatment was given. Ultra-violet light was chosen for the treatment of the control series because it was already the routine method employed in the hospital. There is a considerable literature indicating its value in the treatment of erysipelas. Publications by Fantus (1934), Titus (1934, 1934a), Sutherland and Day (1935), and Lavender and Goldman (1935) may be cited in evidence. The first 161 cases were, in order of admission, allocated to three special groups. Group 1 received treatment only by ultra-violet light; Group 2 only by prontosil; Group 3 both by ultra-violet light and by prontosil. The fatality rate when 161 cases had been admitted was exceptionally low, and as two-thirds of the series had received prontosil it was thought advisable to alter the proportion of cases treated with this drug. Therefore the second 151 cases were divided into three groups, of which the first two were the same as before, but the cases in the third group received treatment solely with Messrs. Burroughs Wellcome's concentrated scarlet fever antitoxin (globulin fraction).

The numbers in each section vary slightly, since six cases were removed. In these it was considered, after further observation, that the original diagnosis of erysipelas was doubtful. Thus the actual numbers in the treatment groups are: ultra-violet light, 104; prontosil, 106; U.V.+ P., 54; antitoxin, 48. As the cases which received ultra-violet light or prontosil in the first series of 161 are strictly comparable to those similarly treated in the second group of 151, comparison is permissible between the cases receiving ultra-violet light and prontosil in the first series and those treated by scarlet fever antitoxin in the second group.

Details of Treatment

Ultra-violet Light.—A portable mercury-vapour lamp (Messrs. Kelvin, Bottomley, and Baird) was used at a distance of twelve inches from the margin of the lesion. For female cases the exposure was of eight minutes' duration, equal to one and a half erythema doses; for male cases the exposure was for ten minutes—in each case once daily. Exposures were repeated at intervals of twenty-four hours when considered necessary. The average number of exposures per case was 2.6.

Prontosil.—The original prontosil "red" of Messrs. Bayer Products, Ltd., was used. Treatment was begun on admission. The drug was given by mouth. The dosage was 1, 2, or 3 tablets of 0.3 gramme each at four-hourly intervals, and administration was continued until the temperature became normal, this being according to the original recommendation. The average case dosage was 5 grammes; the minimum dosage was 1.2 grammes, the maximum 15 grammes. Prontosil "soluble" was given by the intramuscular route in ten cases. In four it was the only method of employing the drug—the average quantity given being 1.5 grammes. In the other six prontosil "red" was also given by mouth. In these six cases the average dosage of prontosil "soluble" was 1 gramme in all. Cyanosis occurred in two cases. It was the only toxic effect present in this series. It was not severe, was only of short duration, and did not prevent the resumption of the drug. No saline purgatives or sulphur were used in any of the 312 cases.

Ultra-violet Light plus Prontosil.—This was a combination of the methods of treatment just described.

Scarlet Fever Antitoxin. One dose was given on admission, either by the intravenous or by the intramuscular route. A further injection was given in a few cases only.

* A Report to the Therapeutic Trials Committee of the Medical Research Council.

The average dosage was 30 c.cm., equal to 30,000 units. All the patients were desensitized before the antitoxin was administered.

Records of Results

The following data were noted in each case: sex, age, duration of illness before admission, and whether the disease was primary or recurrent, idiopathic, or traumatic. The local lesion was considered with regard to its site, extent, swelling, painfulness, and tenderness; the patient's temperature and pulse rate were recorded four-hourly; and toxaemia was estimated under the following headings —prostration, headache, state of tongue, insomnia, vomiting, abdominal distension, and delirium. The urine was examined daily. Intercurrent diseases or degenerations were described; complications, relapses, and recurrences were noted. Each case was reviewed daily. In short, a careful attempt was made to record similar observations on each case in a comparative manner.

Assessment of Results

1. The distribution of the individual cases in the different treatment groups must be considered in respect of certain factors known to influence the course of the disease. Those regarded of greatest importance are (*a*) the duration of the disease before admission to hospital; (*b*) the age of the patient; (*c*) the severity of the infection; (*d*) associated diseases. All that need be stated at present is that tables constructed to show the relation of these factors to the types of treatment indicate an even distribution. A statistician who has examined them is satisfied that there was no weighting of any one line of treatment by any of these factors.

2. The question when "cure" is achieved has to be determined. The fatality rate in erysipelas is so low that it cannot be used in a small series of cases to assess the value of a therapeutic measure. It has other disadvantages, to be mentioned later. There is no single clinical feature which can be regarded as a satisfactory criterion of recovery. Cases are seen where the lesion continues to spread after the temperature has become normal; and, again, it is not uncommon for the local lesion to cease spreading while the temperature is still elevated and the patient continues in a toxic condition. In order to arrive at a conclusion in this series of cases attention was paid to the following points from the commencement of treatment: (i) the duration in days of spread of the local lesion; (ii) the duration in days of the primary pyrexia; (iii) the time in days which elapsed until the patient was free from the toxic symptoms. It was felt that the information gained from these observations would allow a comparison to be made between the effects of different methods of treatment.

Results of Treatment

Reference to the second paragraph under the heading "Plan of Investigation" will show that the number of cases treated with either ultra-violet light or prontosil alone is approximately double that of cases treated with ultra-violet light plus prontosil or with scarlet fever antitoxin alone. This must be borne in mind when considering the following tables. In compiling these tables patients who died have been excluded. There were fifteen deaths, and therefore the total number of cases is reduced to 297. The reasons for the exclusion of fatal cases from the first three tables will be mentioned later.

TABLE I.—*Spread of Lesion*

Method of Treatment	0 Days	1 Day	2 Days	3 Days	4 Days	5 Days and Over	Total Cases
Ultra-violet light ..	32 (32.65)	26 (26.53)	17 (17.34)	11 (11.22)	5 (5.1)	7 (7.14)	98
Prontosil	48 (47.06)	36 (35.29)	16 (15.69)	1 (0.98)	1 (0.98)	0	102
U.V. light + prontosil	19 (35.85)	26 (49.06)	7 (13.21)	0	1 (1.89)	0	53
Antitoxin	14 (31.81)	7 (15.91)	10 (22.73)	9 (20.45)	4 (9.09)	0	44

The figures in parentheses are percentages.

Table I shows a slightly more favourable result as regards cessation of spread in those cases which received prontosil, either alone or in combination with ultra-violet light. Thus the proportion of cases which showed no spread in the lesion after the end of the first day are: ultra-violet light, 59 per cent.; prontosil, 82 per cent.; U.V.+ P., 85 per cent.; antitoxin, 48 per cent. After two days in hospital the lesion continued to spread in only 2 per cent. of all cases receiving prontosil, but with the other forms of treatment the lesion continued to spread in 25 per cent.

TABLE II.—*Duration of Primary Pyrexia*

Method of Treatment	Duration of Pyrexia in Days								Total Cases
	0	1	2	3	4	5	6	More than 6	
Ultra-violet light	9	16 (17.98)	27 (30.34)	12 (13.48)	11 (12.36)	4 (4.49)	9 (10.11)	10 (11.24)	98
Prontosil ..	10	37 (40.22)	33 (35.87)	14 (15.22)	2 (2.17)	5 (5.43)	0	1 (1.09)	102
U.V. light + prontosil	2	18 (35.29)	20 (39.22)	8 (15.69)	2 (3.92)	0	1 (1.96)	2 (3.92)	53
Antitoxin ..	4	10 (25)	4 (10)	2 (5)	7 (17.5)	5 (12.5)	6 (15)	6 (15)	44

The figures in parentheses are percentages given after deducting those cases which were apyrexial.

Table II shows a slightly more favourable result as regards duration of pyrexia in those cases which received prontosil either alone or in combination with ultra-violet light than in the others. Thus after deducting the cases which were apyrexial the percentages of those with no fever after forty-eight hours' treatment are: ultra-violet light, 49; prontosil, 76; U.V.+ P., 74.5; antitoxin, 35. Pyrexia continued for more than three days in only 8 per cent. of all cases receiving prontosil, but with the other forms of treatment the equivalent percentage was 41.

TABLE III.—*Duration of Toxaemia*

Method of Treatment	Duration of Toxaemia in Days								Total Cases
	0	1	2	3	4	5	6	More than 6	
Ultra-violet light	11	12 (13.79)	22 (25.29)	19 (21.84)	15 (17.24)	6 (6.9)	4 (4.59)	9 (10.34)	98
Prontosil ..	5	18 (18.56)	40 (41.24)	22 (22.68)	7 (7.22)	7 (7.22)	1 (1.03)	2 (2.06)	102
U.V. light + prontosil	3	11 (22)	18 (36)	8 (16)	6 (12)	3 (6)	2 (4)	2 (4)	53
Antitoxin ..	5	4 (10.26)	4 (10.26)	5 (12.82)	8 (20.51)	7 (17.95)	5 (12.82)	6 (15.38)	44

The figures in parentheses are percentages given after deducting those cases in which there was no toxaemia.

Table III shows a slightly more favourable outcome as regards duration of toxaemia in those cases which received prontosil either alone or in combination with ultra-violet light. Thus after deducting the cases with no assessable degree of toxaemia the percentages of those free from signs of toxaemia at the end of forty-eight hours' treatment were: ultra-violet light, 39; prontosil, 60; U.V. + P., 58; antitoxin, 16. After three days in hospital 21 per cent. of all cases receiving prontosil remained toxic; the equivalent percentage with the other forms of treatment was 39.

In the paragraph "Records of Results" the component elements investigated under the heading of toxaemia are given. While it is admitted that the precise duration of toxaemia is difficult to assess clinically, the observations were all made and recorded by the same individual. It is therefore considered that they have a certain comparative value.

Some further points now call for consideration.

Recurrence

Table IV shows the number of recurrences which took place in each treatment series. Deaths are not excluded from this table; accordingly the total is 312 cases.

TABLE IV.—*Recurrences*

Method of Treatment	Number of Recurrences	Total Cases
Ultra-violet light	12 (11.5%)	104
Prontosil	9 (8.5%)	106
U.V. light + protonsil	3 (5.5%)	54
Antitoxin	3 (6.3%)	48

No significant difference was found in this series that would point to the action of prontosil in preventing recurrences. It must be remembered, however, that treatment of all types was given during the acute stage only, and was not maintained after the subsidence of the local lesion and the cessation of fever and toxaemia. In a further series we are now undertaking instead of prontosil "red" a variety of the colourless sulphonamide is being used, and there will be a longer period of treatment with the drug in the hope of lessening the incidence of recurrence.

Complications

Table V shows the incidence of those septic complications directly attributable to infection with erysipelas. Among such conditions are abscess formation, septicaemia, thrombosis, and nephritis. Deaths are included in this table.

TABLE V.—*Cases Showing Complications*

Method of Treatment	Number of Cases showing Complications	Total Cases
Ultra-violet light	32 (30%)	104
Prontosil	23 (21%)	106
U.V. light + prontosil	14 (26%)	54
Antitoxin	20 (41.6%)	48

Although there is a lower complicated-case rate in the patients treated with prontosil, the percentage is higher where prontosil and ultra-violet light are used together. In the prontosil-treated groups, however, the combined incidence of complications is 23.1 per cent., in the other treatment groups the combined incidence of complications is 34.2 per cent. This difference is suggestive.

One type of complication deserves special mention. The incidence of nephritis in the four treatment groups is: ultra-violet light, seven cases; prontosil, *nil*; U.V.—P., one case; antitoxin, *nil*. It has been suggested that prontosil may have an irritant effect on the kidneys: this is not borne out by these figures.

The question of associated diseases—metabolic, degenerative, or infective—must also be considered. This factor is difficult to present succinctly, and is, on the whole, associated with the age groups. From an examination of the case records it is not thought to be of any importance in this series as regards the prolongation of the course of erysipelas, but it is of considerable importance with respect to the percentage of deaths.

Deaths

The number of deaths was fifteen out of 312, a percentage of 4.8. This is low if compared with the annual fatality rate given for Ruchill Hospital in the medical

TABLE VI.—*Details of Fatal Cases*

Sex and Age	Treatment	Amount of Therapeutic Agent administered	Complicating Diseases	Days in Hospital	Remarks
M. 50	Ultra-violet light	3 doses; 2nd, 3rd, and 4th days	Nil	4	Pyaemia and septic arthritis confirmed p.m. Blood culture, positive strep
F. 74	"	3 doses; 5th, 6th, and 7th days	Chronic myocarditis	2	Auricular fibrillation. No p.m.
F. 54	"	3 doses; 3rd, 4th, and 5th days	Carcinoma of pharynx being treated with radium needles	3	No p.m.
M. 69	"	3 doses; 4th, 5th, and 6th days	Chronic myocarditis	11	Bronchopneumonia and nephritis. No p.m.

M. 57	"	30 c.cm. IM.	Chronic myocarditis	2	No p.m.

officer of health's annual returns. The percentages there for the past few years are: 1935, 7.5; 1934, 7.6; 1933, 9.3; 1932, 9.6; 1931, 7.7. These percentages include all patients classified in the hospital returns as cases of erysipelas, which represent two-thirds of all notified cases in Glasgow, amounting to about 670 admissions a year. A number of cases so classified have been omitted from the present series where there was doubt as to the clinical diagnosis. This makes the figures difficult to compare.

A point of general interest which has been noted in connexion with similar work conducted on other diseases may be mentioned—namely, that an investigation of this type is undoubtedly beneficial to the cases as a whole. The nursing and medical staff are keenly interested; observation is more acute and sustained; and complaints and complications are watched for and dealt with immediately.

The fifteen deaths are distributed as follows: ultra-violet light, six; prontosil, four; ultra-violet light and prontosil, one; antitoxin, four. These figures must be considered along with causes of death and the complicating diseases. Table VI gives the relevant information.

It is obvious that the cases which ended fatally ought not to be included in the tables concerned with the assessment of the results of treatment. Otherwise a patient who died on the second day in hospital would be shown to have ceased to exhibit spread of lesion, pyrexia, and toxaemia on the second day. It is apparent from these data that no definite conclusions can be drawn from the fatality rate as to the relative values of the different methods of treatment. Death is often determined by the combination of erysipelas and some other disease. Nevertheless in the series of 160 cases receiving prontosil alone or combined with ultra-violet light the fatality rate was 2.5 per cent., while in the 152 cases not receiving prontosil the fatality rate was 6.6 per cent.

Discussion

There is little to add to the comments already made on the data presented. We would emphasize the difficulties attendant on drawing conclusions from the treatment of a disease so variable in its severity as erysipelas. Among important variables difficult to assess are the virulence of the infection and the natural resistance of the patient. In this connexion the general bodily health of the patient and the presence or absence of associated conditions—metabolic, degenerative, or infective—are of consequence. A very large series indeed would be required before one could assert that all such factors were evenly distributed. The cases were arbitrarily grouped in grades of severity, termed mild, moderate, or severe; since mild and moderate grades of infection will tend to recover spontaneously, it was thought that more valuable information might be obtained by considering in detail the cases grouped under the heading "severe." The total number of such cases was, however, only forty-nine, spread over the four treatment groups. This number is too small to permit of any deductions being made from it alone, although the results are in favour of prontosil treatment.

We can state that in this series, so far as we can detect, no known factor is unduly preponderant in one group of cases, and the cases in the different groups seem to us reasonably comparable. Nevertheless, while it is desirable that the therapeutic trial of a new drug should be made on statistical evidence as far as possible, there is a place for the expression of a clinical opinion. In five of the cases originally entered in the prontosil groups the condition on admission was so severe that a fatal result would not have been unexpected. It was felt that prontosil definitely contributed to their recovery. One case which was originally in the ultra-violet group showed uncontrolled spread with high pyrexia for six days, and was in the typhoid state when it was decided to employ prontosil; the patient's recovery was completely unexpected. This case has been left in the ultra-violet light series and does not affect the percentages in the tables. Two further cases in the ultra-violet light series also received prontosil at a later date. These likewise do not affect the percentages.

The benefits due to prontosil in erysipelas are statistically assessable and are great enough to render the use of such drugs advisable in this disease until some better form of treatment is available, but the action cannot on the whole be termed dramatic.

Conclusions

1. A series of 312 cases of erysipelas was treated under controlled conditions with (*a*) ultra-violet light; (*b*) prontosil; (*c*) ultra-violet light and prontosil; or (*d*) scarlet fever antitoxin.

2. There was an even distribution of the individual cases in the treatment groups in respect of factors known to influence the course of the disease, such as (*a*) the duration of the disease before admission to hospital; (*b*) the age of the patient; (*c*) the severity of the infection; (*d*) associated diseases.

3. The average case dosage of prontosil was 5 grammes; the average duration of prontosil treatment was two days. Treatment was given during the acute stage only, and was not maintained after the subsidence of the local lesion and the cessation of fever and toxaemia.

4. The cumulative evidence indicates that those cases which received prontosil showed better results in respect of curtailment of (i) the duration of the spread of the local lesion; (ii) the duration of primary pyrexia; (iii) the duration of toxaemia.

This study was undertaken at the request of the Therapeutic Trials Committee of the Medical Research Council. We are indebted to Messrs. Bayer Products, Ltd., for the supplies of prontosil "red" and of prontosil "soluble." The χ^2 values and standard errors of the tables have been calculated by Dr. P. L. McKinlay, Medical Officer, Department of Health for Scotland. The statements made in the text are all borne out by the values found. We wish to express our thanks to him for his services. We are also indebted to Dr. W. M. Elliott, superintendent of the Ruchill Fever Hospital, for permission to carry out this investigation.

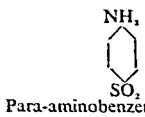
The scientific exhibits at the Paris International Exhibition are grouped in the Grand Palais (Champs Elysees), which has been incorporated as part of the exhibition under the title "Palace of Discovery." Here exhibits from all parts of the world demonstrate scientific progress throughout the centuries. Sections are devoted to physics, chemistry, medicine, and surgery, and to each of these important contributions have been made by the Wellcome Historical Medical Museum. They include a collection of stethoscopes, showing the development of the instrument from the time of its invention to the present day, an exhibit showing the evolution of the clinical thermometer, and another illustrating the history of the transfusion of blood.



AGRANULOCYTOSIS AND PARA-AMINO-BENZENE SULPHONAMIDE

BY

C. J. YOUNG, M.B., D.T.M., D.P.H.

(From the Pathological Department, Bradford Royal Infirmary)

Kracke and Parker (1933, 1934) presented evidence that agranulocytosis might be caused by certain drugs, notably amidopyrine, phenacetin, certain gold salts, and arsphenamine. They pointed out that structurally these drugs possess in common the benzene ring with an attached NH_2 or amine group, which increases the ease of oxidation. A consideration of the formula of sulphanilamide suggested to us the possibility that this drug might

Para-aminobenzene sulphonamide.

also be capable of producing agranulocytosis. The matter appeared to be one of importance for various reasons. First, if the drug reduced the polymorph concentration in the blood in cases of infection against which it was therapeutically ineffective, it might affect unfavourably the course of the disease. Secondly, sulphanilamide is used in acute infections which are not infrequently fatal, and where the latter outcome resulted from agranulocytosis this might readily escape observation. Thirdly, the drug is available to the general public and has received considerable publicity in the lay press.

It was decided, therefore, to make observations on the leucocytes in sulphanilamide-treated patients. Complete agranulocytosis with fatal result occurred in the second case investigated. While the possibilities are obvious, it naturally cannot be determined whether this occurrence was or was not due to the administration of this drug.

Case of Agranulocytosis

The patient was a man of 53 suffering from acute rheumatism with joint pains and pyrexia. There was a history of previous attacks in 1901, 1908, and 1914. The condition failed to respond to salicylates, and prontosil album (3 grammes daily for eighteen days) was given. At the end of this period the clinical condition had deteriorated, the temperature running at a higher level than before, and treatment was stopped. Four days afterwards complete agranulocytosis was found, and blood culture, which had given no growth three weeks previously, now gave haemolytic *Staphylococcus aureus* and *Streptococcus viridans*. The patient died the following day.

The treatment administered is summarized in Table I, and the haematological observations in Table II.

TABLE I.—*Drugs administered*

Date	Drug	Dosage
8–11/4/37	Sodium salicylate	60 grains daily

* 26/5/37, post-mortem counts, three hours after death: red cells, 4,290,000; reticulocytes, 75,000; platelets, 141,000 per c.mm.

† Percentage of polymorphs showing toxic granulation.

All counts were made about the same time each morning.

Skin rashes occurred on April 14 and May 12, 21, and 24. Traces only of albumin were found in the urine on four occasions.

Post-mortem Findings

The post-mortem examination was made three hours after death. An inflammatory lesion covered with greyish-white membranous exudate was present in the pharynx, showing a patchy distribution over the sides and posterior surface of the pharynx and posterior surface of the epiglottis. The membrane consisted of the necrosed superficial tissues infiltrated with masses of cocci. Collections of lymphocytes were present but no polymorphs. Bacteriological examination showed the predominating organisms to be haemolytic *Staphylococcus aureus* and *Streptococcus viridans*, and was negative for diphtheria.

The blood in the heart was not coagulated, so allowing counts to be made. A few minute nodules due to simple non-ulcerative endocarditis were present on the mitral valve and were presumably of rheumatic origin; no bacteria were observed in them.

The right kidney showed a moderate hydronephrosis due to an aberrant artery, but only slight damage to the renal structures was found microscopically. The liver (1,555 grammes), spleen (175 grammes), and other organs revealed nothing of note.

Bone Marrow.—The distribution of red marrow was normal, being present in vertebra, sternum, and ribs, while that in the right tibia and femur was fatty, only the head of the femur and upper part of the shaft showing some pink coloration. Microscopically there was a complete absence of all granular cells, both neutrophil and eosinophil, while cells of the lymphocyte series, mega-

karyocytes, and nucleated red cells were numerous in the red marrow. Spectroscopic examination of the blood for sulphaemoglobinaemia was negative. Death was considered to be due to agranulocytic angina with septicaemia.

Discussion

Between May 3 and 21 54 grammes of prontosil album were given. Agranulocytosis developed some time between May 20 and 25. A feature of the case was the failure of serial leucocyte counts to give warning of the impending disaster, the changes being merely those of a progressively active infection. An increased output of young polymorphs (Arneth classes I + II, Table II) was well maintained till May 20, after which a rapid failure in their production evidently occurred. The types of myeloid bone marrow found in cases of agranulocytosis include aplastic, normal, and hyperplastic varieties (Beck, 1933). The present case belongs definitely to the aplastic type.

Of the various drugs administered, chloral and the barbiturates do not contain the benzene ring. Barbiturates have been frequently used in association with amidopyrine in recorded cases, and an adjuvant effect has been suggested, but available evidence is against their being independently effective. Salicylates contain the benzene ring with no amino group; there is little evidence that they can cause agranulocytosis, and in any case none had been given within twenty-four days of the onset of the condition. Kracke (1932) produced experimental agranulocytosis in rabbits with benzene, but concluded that oxidation products were probably responsible. Kracke and Parker (1934) later recorded that there was constantly increasing evidence that the condition was caused for the most part by easily oxidizable benzene-ring drugs.

Marshall, Emerson, and Cutting (1937) have investigated the excretion of sulphanilamide, and found that 100 per cent. of the daily dose could frequently be recovered in the urine as free sulphanilamide and a conjugated form—para-acetylaminobenzene sulphonamide. They add, however, that it is possible under certain conditions that a small amount is excreted in some other form or eliminated through some other channel than the kidneys. They showed in a case with impaired renal function that there was delay in excretion of the drug.

Cases of agranulocytosis have been recorded in which no drugs appear to have been taken and no obvious cause could be found, so that a definite conclusion in regard to the causation in the present case is not justified.

Summary

1. A case of fatal agranulocytic angina is recorded.

2. The bone marrow showed complete myeloid aplasia.

3. The only benzene-ring drug administered within twenty-four days of the development of agranulocytosis was sulphanilamide.

4. The agranulocytosis appeared to be either of the idiopathic type of unknown aetiology or to be due to sulphanilamide.

I am indebted to Dr. J. K. Rennie for the clinical material and data, and to Dr. J. A. Price and Mr. G. C. Holliday for assistance with some of the investigations.

FOOD POISONING—ITS EPIDEMIOLOGY AND BACTERIOLOGY*

BY

E. R. JONES, M.D., D.P.H., F.I.C.
Senior Pathologist, Kent County Council

The term "food poisoning" is conventionally restricted to an acute gastro-enteritis caused by the ingestion of food or drink which either contains living bacteria capable of setting up an acute inflammatory condition of the alimentary tract or contains toxic substances produced by various types of bacteria that have an irritant effect upon the gastro-intestinal mucosa. This definition does not include "botulism," a disease which presents no symptoms of gastro-enteritis, but which is nevertheless a form of food poisoning caused by the absorption from the alimentary canal of a specific toxin elaborated under suitable conditions by the *Clostridium botulinum*.

During recent years the number of organisms proved to be capable of giving rise to food poisoning in one or other of its forms has greatly increased. Since the isolation of *B. enteritidis* by Gaertner in 1888—followed ten years later by the isolation of *B. aertrycke*, or *Bact. typhi murium* as this organism is now called, by Durham in England and de Nobele in Belgium, both organisms being undoubtedly responsible for cases of food poisoning—at least twenty-seven members of the Salmonella group have been identified with actual outbreaks of food poisoning in human beings. It is of importance to note, too, that some pathogenic intestinal organisms normally giving rise to one particular type of disease may on occasion cause another kind of illness—for example, the dysentery organisms may produce the typical symptoms of food poisoning.

It is difficult to assess with any degree of accuracy the prevalence of food poisoning. Many solitary cases must undoubtedly go undetected, but with increased laboratory facilities such cases are being detected with greater frequency. In some form or other cases occur fairly often in this country—for example, fifty-eight outbreaks were recorded at the Ministry of Health in 1934, and of 137 outbreaks of suspected food poisoning in 1935 only twelve were excluded as not food poisoning. In America and Germany the incidence seems to be considerably higher.

Food poisoning may be conveniently discussed under three headings: (1) that due to the multiplication within the body of pathogenic bacteria present in food, and referred to as the "infection" type; (2) that due to the ingestion of certain substances formed as the result of bacterial multiplication in the food before ingestion—the "toxin" type; and (3) that due to the toxin of *Clostridium botulinum*—"botulism."

The "Infection" Type

Among the organisms responsible for the "infection" type members of the Salmonella group are the most common, but members of the dysentery group, more especially the Sonne bacillus and *B. dysenteriae* Flexner, must be included. In 1934 Salmonella infections were discovered in twenty-two instances, of which fourteen were, so far as could be ascertained, solitary cases, and during 1935 these were found on fifty-three occasions; twelve outbreaks during the latter year, however, were caused by dysentery bacteria, of which eight were due to the Sonne bacillus, three to *B. dysenteriae* Flexner, and

* Paper read at the Congress of the Royal Institute of Public Health and Institute of Hygiene, Margate, 1937.

one to the Newcastle–Manchester type of dysentery organisms. An outbreak of acute gastro-enteritis affecting about eighteen individuals who had partaken of cockles presumably contaminated with *Proteus vulgaris* is recorded by Dr. Allan Gray (1937).

I have included in the Salmonella group only those organisms which give rise to acute gastro-enteritis, as distinct from those causing the "enteric" type of disease. By some authorities *B. typhosus* as well as the paratyphoids are placed together in the Salmonella group; and from antigenic analysis this is quite justifiable. The "O" or somatic antigen of *B. typhosus* is exactly the same as the somatic antigen of *B. enteritidis* and its numerous varieties; *B. paratyphosus* B has the same somatic antigen as *B. aertrycke, stanley, derby, reading,* and so on. But in other respects the enteric group differ greatly from those I have included in my Salmonella group: the incubation period of the disease they produce is considerably longer, the symptomatology is different, the enteric group are not natural pathogens of animals, and transmission of the disease is confined ultimately to the human carrier. In fact, the whole problem of the prevention of enteric fever consists in stopping the various routes by which the bacteria may pass from the intestine of one human being to the mouth of another, whereas in the food-poisoning organisms there are additional factors to consider.

But seeing that all these bacteria are so closely related antigenically it is not surprising that some of them give rise on occasion to one type of disease and on occasion to another—for example, *Bact. cholerae suis,* var Kunzendorf, often known as the Western European type of *paratyphosus* C or *Bact. suipestifer,* usually gives rise to a continued fever of the enteric type, but infection may take the form of an acute gastro-enteritis; and, similarly, *Bact. typhi murium* or *B. aertrycke,* though generally causing an acute gastro-enteritis, does occasionally bring about a continued fever. Even varieties of the same type of organism may cause different symptoms—for example, there are eight varieties of *Bact. enteritidis,* most of them antigenically similar and differing from one another only in some of their fermentation reactions (the Stern glycerol reaction, Bitter's rhamnose fermentation test, and *d*-tartrate fermentation reaction). Some of these give rise to the enteric type of disease and others to acute gastro-enteritis. Some time ago I was able to isolate *Bact. senftenberg,* var. Newcastle, from the faeces of a patient who showed the typical symptoms of a paratyphoid infection. An extract from his case sheet on admission to hospital on July 10, 1935, reads: "In bed since the 4th inst., complained of severe frontal headache; patient appeared very ill, feverish; rash fairly well marked over the body, but brighter over the arms, wrists, and legs. Temperature 101.6°, pulse 120, respirations 26. History of constipation; complains of pains and stiffness over the arms, shoulder-joints, and legs." The patient's serum agglutinated Oxford Standards Salmonella group suspension only up to a dilution of 1 in 320, with no agglutination with *paratyphosus* A or *paratyphosus* B suspensions.

In the case of *Bact. thompson,* I have isolated this organism from the faeces of two patients in different parts of this county during the past twelve months; the cases were quite unrelated and both were fatal. Each showed the symptoms of *B. typhosus* infection, but no Widal examination was made. When I rang up the doctor in one case he was rather surprised at the result: the patient had died the previous day, and the doctor had just filled in the death certificate, recording the death as due to typhoid fever. It might be argued that his patient died of a typhoid infection and that *Bact. thompson* was accidentally found in the faeces. I cannot prove or disprove this, but the only really reliable proof of infection is the isolation of the organism from the patient, and, in the case referred to, *Bact. thompson* was obtained in large numbers on primary culture direct from the faeces by a method which has been tested out carefully and found capable of detecting typhoid organisms when these are relatively very very few.

The dysentery organisms, as I have mentioned, occasionally behave in a similar manner; instead of the usual dysentery symptoms the patient may show the symptoms of acute gastro-enteritis. This, of course, is mainly a problem which concerns the laboratory; it is the duty of the laboratory to identify any pathogenic organism that may be present, and not confine its search to members of one particular group. But it is as well to remember that all cases of continued fever need not essentially be due to a typhoid or paratyphoid infection. And as dysentery organisms may occasionally cause food-poisoning symptoms, these must be kept in mind; they are somewhat delicate organisms, rather apt to die off very quickly outside the human body, so that infected or suspected material should be examined as early as it is available if it is hoped to isolate them. I have found that the method of adding two parts of 30 per cent. glycerol in 0.6 per cent. saline to 1 part of faeces as soon as possible after they are passed helps to keep the dysentery bacteria alive when the services of a laboratory are not immediately available. As far as I know there is no good selective medium invented yet for the isolation of dysentery organisms, but my experience is that the methylene blue–eosin agar used in the examination of acid and gas producers in water is slightly superior to MacConkey's medium.

As has been indicated, the Salmonella group consists of a large number of organisms, and new types are continually being added to the list, but the commonest type in food-poisoning outbreaks is undoubtedly *Bact. typhi murium* (*B. aertrycke*). During the years 1923–33 the Ministry of Health found this organism in 110 out of 186 food-poisoning outbreaks, and in 1934 in twenty-two out of forty-three; of the forty-six outbreaks that occurred in 1935 in which the causative organisms were actually isolated twenty-nine were due to *Bact. typhi murium.* The next most frequently isolated organism is *Bact. enteritidis.* These facts are rather significant, and are of some importance when the cause of outbreaks comes under investigation.

The "Toxin" Type

In spite of exhaustive investigations into many outbreaks it has not been possible to isolate any member of the food-poisoning or dysentery groups. These outbreaks were formerly designated as ptomaine poisoning, caused by the presence in the ingested foods of products of protein decomposition. These so-called ptomaine poisons or toxic amines, however, are not produced until the food reaches an advanced stage of decomposition, and further examination showed them to be relatively non-toxic to most laboratory animals except when given in excessively large doses, far larger than are ever likely to be ingested under natural conditions. Barber in 1914 described a very interesting outbreak where a certain strain of *Staphylococcus albus* was isolated from the milk of a cow. The milk produced no ill effects if consumed immediately after its withdrawal from the udder, but on

being allowed to stand a few hours at room temperature it invariably produced the characteristic symptoms of acute gastro-enteritis. That these results were not due to any other component of the milk was proved by the fact that the same symptoms were produced in human volunteers who drank pure milk into which this particular strain of staphylococcus was introduced. The organism itself obviously did not cause the symptoms: it was necessary to allow it time—two or three hours at 28° to 30° C.—in which to produce something that would give rise to symptoms. Dr. Savage (1920) suggested later that many of the outbreaks from which food-poisoning organisms could not be isolated might be due to the ingestion, not of food-poisoning organisms themselves, but of toxic products elaborated by them, and recent work in America and in this country has furnished evidence strongly supporting this view.

The experimental evidence that staphylococcal toxin does produce gastric irritation has been provided mainly by Professor Jordan of Chicago, and consists in the production of the characteristic sickness and vomiting in human volunteers and in monkeys on the administration of quite small doses by the mouth. Savage and White (1925) paid considerable attention to this aspect of food poisoning in their extensive and valuable investigations, and while the implication of the Salmonella group in some of these "toxin" outbreaks was difficult to prove, it was nevertheless highly probable that these were the responsible organisms. Twenty-six of these "toxin" outbreaks are recorded in the Annual Report of the Chief Medical Officer for the year 1934 and forty-seven the following year.

Very little has as yet been discovered as to the nature of these toxic substances. It is not known whether they are specific bodies elaborated by the bacteria or whether they represent the breakdown products of the dead organisms. They appear to be relatively non-toxic when fed to most laboratory animals, though young rhesus monkeys are usually affected after a fairly large dose. On the whole, they are weakly antitoxinogenic. Savage and White were able to show that when toxic canned foods were emulsified and injected into animals, feebly agglutinating sera for Salmonella organisms were sometimes obtained, but, in spite of the intense symptoms these toxic foods produced, the sera of sufferers seldom revealed any appreciable developments of agglutinins. In their "Study of 100 Recent Outbreaks of Food Poisoning," they recorded that in nine of the outbreaks, while no specific organisms were isolated, the presence of Salmonella toxins in the suspected food was highly probable. Samples of blood from some of the patients showed a slight agglutination with members of the Salmonella group, usually up to a dilution of 1 in 20 or 1 in 25. Injections of watery extracts of the food into animals intraperitoneally sometimes resulted in the development of agglutinins; but here again positive agglutination was obtained only up to dilutions of about 1 in 40. The evidence, as may be gathered, is not too conclusive, but taken in conjunction with other factors it lends great support to the "toxin" theory.

Bacteria capable of giving rise to these toxic substances are not by any means confined to members of the Salmonella group; many are regarded as non-pathogenic under ordinary conditions, but with certain conditions of growth they are capable of producing these highly irritant toxic substances. *Staphylococcus aureus* is the organism most frequently associated with these "toxin" outbreaks; others are *Staphylococcus albus, B. coli, Proteus vulgaris, Proteus morgani, Streptococcus viridans,* and a micrococcus found in milk. Not all members of any particular group have the power to produce these substances—for instance, only a very few staphylococcal strains possess this particular property, and the toxin is quite distinct from the haemolytic or necrotic toxins of the staphylococcus. Up to the present we have no means, other than the direct test on human volunteers or susceptible monkeys, of determining which strains are toxinogenic and which are not. It is presumed that the bacteria multiply and elaborate these substances in the food prior to its consumption, the subsequent cooking to which the food is subjected destroying the organisms without materially affecting their toxic products. A consideration of the ubiquity of some of these bacteria, the variation in the potency of the toxins they produce, our inability at present to distinguish the poisonous from the non-poisonous strains except by test on the human subject, and our comparative ignorance of the suitable conditions for the production of toxins, makes this type of food poisoning not only difficult to investigate but also difficult to control.

The seasonal variation of food poisoning of the "infection" type is in all probability only a consequence of rise of atmospheric temperature favouring bacterial growth in infected foods, and thus encouraging the ingestion of large doses of the specific bacteria that seems to be necessary to set up the acute symptoms. The highest incidence occurs between the months of May and October, with the peak incidence in July. In the "toxin" type, too, more outbreaks tend to occur during the summer months, but these are far more evenly distributed throughout the year.

In both types the morbidity rate is high: 75 to 100 per cent. of the persons who eat the affected food are attacked, but the mortality rate is very low. The symptoms produced by the "toxin" type are similar to those of the "infection" type: the incubation period is usually shorter—half an hour to four hours, as compared with six to twenty-four hours in the latter. While they last the symptoms in the "toxin" type are more marked, but recovery is usually more rapid and the patient is well again in two or three days.

Vehicles of Infection

In Salmonella infections made-up meat dishes are the commonest vehicles of infection. In twenty-eight cases in which the causative organisms were isolated by Savage and White (1925) ten were caused by made-up meat dishes. Fresh meat, manipulated meat, milk, and milk products, especially ice-cream, are others; fish and fresh eggs, particularly ducks' eggs, have often been found to be responsible. The food associated with the "toxin" type is usually some form of canned meat or potted meat or fish, and milk products, more especially cakes and éclairs filled with cream or custard. "Corned beef" outbreaks are much less frequently met with now than formerly, the more efficient modern methods employed in the canning of this foodstuff being probably responsible for the almost complete disappearance of this one-time common source of "toxin" outbreaks. Obviously any food may act as a vehicle of infection, as, for instance, a dried milk powder from which *Bact. typhi murium* was isolated by Jones and Wright (1936).

Those familiar with the investigation of food-poisoning outbreaks will know that for various reasons it is not always an easy matter to isolate the offending organism or to prove the presence of a specific toxin; much less easy is it to trace the mode of infection of the food by

the organism. The common ways in which food may be infected are: (1) Infected animals may be used for food—for example, meat (beef and pork), ducks or their eggs. (2) Infected animals may excrete specific organisms to contaminate food—for example, rats and mice, bovines. (3) Human carriers may contaminate the food by handling.

There seems to be little doubt that animals, especially cattle and pigs, may suffer from diseases caused by the Salmonella organisms. The disease in animals is usually of an acute and often fatal type, but the carcass need not essentially be noticeably unhealthy. A case is reported in the annual report of the Ministry of Health, 1935, in which beef from the carcass of an animal almost certainly suffering from a Salmonella septicaemia was responsible for 174 cases, with eight deaths, in Lancashire. The flesh appeared normal, but *Bact. typhi murium* was isolated from all the parts of it examined. In most cases of food poisoning due to the consumption of meat from an infected animal it has been found that the animal has been "emergency slaughtered." Meat from such a source must be eaten in an uncooked or imperfectly cooked condition, as sausages or pressed beef, to cause ill effects. In this country such occurrences must be extremely rare, but in Germany, where more raw meat is eaten, they afford a frequent source of human infection. Within recent years ducks' eggs have on many occasions been responsible for food poisoning: one such outbreak investigated by Dr. Scott of the Ministry occurred in this county in 1933, and an outbreak at Preston in 1934 involved 250 persons who had consumed ice-cream in the preparation of which, it was alleged, the mixture containing ducks' eggs was insufficiently cooked. Infection of ducks by *Bact. typhi murium* and *Bact. enteritidis* is not uncommon; hens are less frequently infected with these organisms.

The contamination of foodstuffs by the excreta of infected animals is probably of more frequent occurrence than is generally supposed. McAllan and Howie (1931) record an outbreak of Salmonella infection in which milk was contaminated from the faeces of an infected cow; but rats and mice, in my opinion, are commoner offenders in this respect. Our rodent population is a fairly large one, and both rats and mice suffer naturally from infection with *Bact. typhi murium* and *Bact. enteritidis*, and may excrete the organisms in their urine and faeces for considerable periods. Food exposed in insanitary premises invariably attract these animals, and infection is thereby easily transferred to human beings. In the case of the infected dried milk referred to previously, the food used for a child who subsequently died of an *aertrycke* infection was kept in an uncovered container. Mouse faeces were found in the food, and from these pellets as well as from the powder *Bact. typhi murium* was isolated. From the intestines of mice caught in the house within the next few days the same organism was cultured. In an investigation commenced some time ago about 250 rats and mice were examined, and cultures of *Bact. typhi murium* or *Bact. enteritidis* were obtained in from 10 to 12 per cent. of them, in some cases from the intestine, in others from the intestine and spleen.

The Carrier

With regard to the human carrier as a source of infection, it is generally considered that he plays but an insignificant part. Authenticated cases are on record, but the proved cases are relatively few. The probability of the intermittent carrier state makes it still more difficult to ascertain the true condition of affairs. The methods employed in the examination for carriers need to be more exacting than in the examination of the frank acute case. Agglutination tests are of little help; they may narrow the field of "suspects," but even in cases of known infection, proved by the actual isolation of the organism, the agglutinin response may be very poor, and agglutinins may be present to some extent in the blood of normal persons. As I have said, the isolation of the specific organism is the only proof of infection, and obviously in the case of a chronic carrier who is excreting but few pathogenic bacteria as compared with non-pathogenic ones, it is only to be expected that such carriers are easily missed unless special methods are employed. The frequency with which I have accidentally found Salmonella organisms suggests that carriers may be more common than is generally supposed. Two of these cases were particularly interesting. One was that of a missionary who had been invalided home from India with typhoid fever. He walked into the laboratory one morning with a specimen of faeces; he wished to know whether or not he was a typhoid carrier. After a few formalities the specimen was accepted. No *B. typhosus* was found in the specimen but a large number of *Bact. typhi murium*, and the same results were obtained from another specimen taken a week or so later. The other case concerned a possible typhoid carrier in a family of six persons, one of whom had developed typhoid fever, the organisms having been found in her faeces. No typhoid organisms were recovered from any of the other five persons, but a good growth of *B. aertrycke* was obtained from the faeces of the father, who was quite fit and apparently healthy and could not remember ever having been ill.

And here I must digress a little again to mention the methods employed for the isolation of these pathogenic organisms: the matter has an important bearing on the problem of human carriers and also on the prevalence of these food-poisoning organisms among animals. In 1936 I published a paper in which a comparison is given of results obtained with special selective media and with MacConkey's medium—the medium still used in many laboratories. I shall not go into the details of the different media; it will be sufficient to say that in a very careful investigation of a large number of specimens, both faeces and urines, 34.7 per cent. of the specimens were positive for organisms of the typhoid food-poisoning group on the particular selective media used as compared with 14.5 per cent. positive with MacConkey's medium. At the time when these special media were being tested out many of the cases to which I have referred came into the laboratory for investigation, and all specimens were examined on both media. In the fatal case of *B. aertrycke* infection due to the contamination of the dried milk by mouse faeces, *B. aertrycke* was isolated on both media from the faeces of the patient and from post-mortem material, but only on the selective media was the organism recovered from the infected food and from the mice themselves. Similarly for the two *aertrycke* carriers and the *senftenberg*, var. Newcastle, case: in all these the pathogenic organism could only be recovered on the selective media. I would mention also that convalescents became negative on MacConkey's medium very much earlier than they did when the faeces and urines were examined on these special media. I had occasion some time ago to investigate a small outbreak of dysentery in a children's hospital. Among the specimens examined were eleven mice caught on the premises. No food-poisoning or dysentery organisms were isolated from

these, but Morgan's bacillus No. 1 was recovered from the intestine of two mice. The part these bacteria play in summer diarrhoea of infants is not yet entirely clear, but there is no doubt that they are the organisms most frequently isolated from these cases. It thus appears to me that the dissemination of pathogenic bacteria by human convalescents and carriers and by rodents can very easily occur, and unless special methods for the examination of these are employed many sources of infection are bound to be missed.

The mode of infection of food by organisms giving rise to the "toxin" type of food poisoning is not so difficult to determine. As has been indicated, many organisms of different types have now been identified with outbreaks; most of them are common organisms found almost anywhere, but their presence in various foodstuffs has hitherto been regarded as of no significance. In the light of our present knowledge, however, in cases where these occur in any suspected food and in which no organisms of the Salmonella group can be isolated it is as well to bear in mind their possible association with the outbreak.

Botulism

Botulism is a disease which is fortunately rare in this country, and while very few of us have had the opportunity of investigating an outbreak of this disease, it is necessary to keep in mind its existence. My experience is confined to the examination of nut-meat brawn at the time of the occurrence of the few cases in London in 1935; neither *Cl. botulinum* nor its toxin was detected in the specimens examined.

The causative organism is a normal inhabitant of the surface layers of the soil, from which it may easily gain access to various types of food. There is no evidence that it is a normal intestinal inhabitant of man or of animals. *Cl. botulinum* is an anaerobic sporing organism which is incapable of growth in the animal body and giving rise to infection, but under suitable conditions it produces a very potent toxin. We do not know all the factors which determine the growth and toxin production of the organism. The spores are fairly resistant to heat and may withstand boiling for from half an hour to twenty-two hours: the potted-duck paste responsible for the Loch Maree cases in 1922 had been heated on three occasions, at one stage to a temperature of 115° C. for two hours. Media which are acid do not encourage growth, so that canned acid fruits are not likely to give rise to botulism. Vegetables and other products that are not acid and are preserved in air-tight containers which are not or cannot be adequately sterilized by heat —for example, glass containers—are possible sources of danger. The toxin is destroyed by such heat as is ordinarily applied in cooking, so that cooked food eaten within a short time of heating, and also fresh foods, are safe.

In Europe most of the cases of botulism have been caused by preserved meat or potted paste, whilst in America the contaminated foods have been mainly canned fruits and vegetables. Investigations into the different outbreaks have indicated that home-canned food is decidedly more dangerous than commercially prepared food.

Food infected with organisms of the Salmonella group usually appears quite normal: there need be no great change in colour and no detectable change in smell or taste. But in the case of botulism the preserved foods are frequently noticeably spoiled, the cans are usually "blown," the food shows evidence of decomposition in varying degree, and it has a more or less rancid odour.

The methods of investigating outbreaks of food poisoning are not within the scope of this paper, and are fully described in a Memorandum by the Ministry of Health (Memo 188/Med. 1935).

Commentary

From what has been said it is obvious that there is still much to learn about bacterial food poisoning in human beings. The paths of infection of food, the part played by animals in transmitting infection, the conditions under which some normally harmless bacteria as well as natural pathogens are able to elaborate substances highly irritant to the human intestine, and the nature of these toxic substances are matters on which our knowledge is still very deficient and imperfect. The problems met with in investigating even the smaller outbreaks are often numerous and complicated, and entail an enormous amount of work that can only be successfully attempted in a well-equipped laboratory. Fortunately the assistance of the Ministry's laboratory is available for the examination by any local authority of specimens from suspected food poisoning.

Comparatively few outbreaks are investigated completely: this is inevitable in some cases, but an outbreak ended is not a problem solved. Very rarely are negative findings published: this is unfortunate, because a clearer understanding of the factors involved in bacterial food poisoning will more easily be acquired only by a comparison and correlation of all findings, whether these be positive or negative, in the different types of outbreaks.

A conference of the Tuberculosis Association will be held in Paris from October 14 to 17 under the presidency of the Ministre de la Santé Publique et de l'Education Physique. The party will leave Victoria Station, London, by the 9 a.m. train on Thursday, October 14, and will arrive in Paris at 3.50 p.m. At 5 p.m. there will be a reception at the Hotel Lutécia by the Comité National de Defense contre la Tuberculose, followed by a dinner under the presidency of the Minister of Public Health. On October 15 visits will be paid to the Hospital Laennec, the Dispensary Léon Bourgeois, the Pasteur Institute, and to the dispensary, crèche, and open-air school at Suresnes. Luncheon will be given by the Municipality of Suresnes. On October 16 there will be visits to the offices of the Assurances Sociales and to l'École de Puériculture, and luncheon will be arranged by the Office of Public Health of the Seine at the Sanatorium of Saint Martin du Tertre. The party will leave Paris at 7.55 p.m., and will arrive in London on the morning of Sunday, October 17. Members of the Tuberculosis Association who wish to attend the conference are requested to inform the honorary secretary, Dr. Frederick Heaf, at 26, Portland Place, W.1, by July 31. All tickets will be issued by Thos. Cook and Son, Ltd., Berkeley Street, W.1, to whom remittances should be made payable and sent direct. Correspondence with Messrs. Cook should be marked B.H.43. Further information can be obtained from the honorary secretary.

SODIUM CHLORIDE CONTENT OF CEREBRO-SPINAL FLUID IN TUBERCULOUS MENINGITIS

BY

JOHN INGHAM, A.I.C.

Biochemist to the Medical Unit, Welsh National School of Medicine, Cardiff

The normal sodium chloride content of the cerebro-spinal fluid is usually taken as 700 to 750 mg. per 100 c.cm., and diminution is practically a constant feature of all inflammatory conditions of the cerebro-spinal nervous system. Although the extent of this diminution is variable, all observers seem to be agreed that it is greatest in tuberculous meningitis. Nobécourt and Voisin (1903) directed attention to this low chloride content in tuberculous meningitis, and Mestrezat (1912) emphasized its diagnostic significance. More recently Fowweather (1930), studying cases of tuberculous meningitis, showed that there was a rapid fall in the cerebro-spinal fluid chlorides concomitant with the progress of the illness. Very divergent figures have been recorded by various investigators, as may be seen from the following table:

	Mg. per 100 c.cm.
Mestrezat (1912)	500–600
Fowweather (1930)	590 and over
Eskuchen (1924)	500–600
Fremont-Smith (1925)	Under 600
Wilcox and Lyttle (1925)	513–690
Neale and Esslemont (1928)	489–763
Benoliel (1925)	765–936
Riser (1929)	500–675
Lattes (1929)	570–640
Fontecilla and Sépulveda (1921)	580
Greenfield and Carmichael (1926)	500–600
Nowicka and Mestrezat (1924)	590
A. Prunell (1935)	504–678

Such a wide variation in figures seems to call for some explanation or reinvestigation.

In the course of routine work in this department 700 mg. per 100 c.cm. was obtained in one meningitic fluid containing tubercle bacilli, but on investigation this high figure was found to be due to the nurse having sterilized the lumbar puncture needle by boiling in saline. The examination was repeated on the following day with fluid withdrawn by a needle which had been sterilized in boiling distilled water, and the sodium chloride content was found to be only 510 mg. per 100 c.cm. On another occasion a high chloride figure resulted from the lumbar puncture needle having been sterilized in the autoclave, the water of which had not been changed for a long time. In other cases the cotton-wool test tube plugs and filter papers used in the test have been found responsible for a fallacious high chloride figure.

In estimating the sodium chloride content of the cerebro-spinal fluid the greatest care is essential to ensure that there is absolutely no possibility of the slightest trace of extraneous saline reaching the fluid from any source whatsoever—needle, test tube, etc., or apparatus used in the test.

The Investigation

With these facts in mind, and paying special attention to technique, the chloride content of the cerebro-spinal fluid of 126 patients was investigated. Of these, eighty-four suffered from tuberculous meningitis, all excepting two showing tubercle bacilli in the fluid, and forty-two were non-tuberculous cases. These latter served as controls and were made up of: (*a*) twenty-six cases of non-tuberculous meningitis—namely, meningococcal meningitis (eleven cases), pneumococcal meningitis (six cases), streptococcal meningitis (three cases), aseptic meningitis (one case), syphilitic meningitis (one case), influenzal meningitis (four cases); (*b*) ten cases of non-tuberculous lesions of the nervous system other than meningitis—namely, poliomyelitis (two cases), polio-encephalitis (two cases), juvenile dementia paralytica (one case), mental defective (post-meningitic) (one case), infantile convulsions (one case), epilepsy (one case), cerebral softening (one case), paraplegia (one case); (*c*) six normal healthy individuals.

Results

NON-TUBERCULOUS CONTROL FLUIDS—CHLORIDE CONTENT

The fluids from the six normal healthy individuals gave the following figures (mg. per 100 c.cm.): 700, 720, 714, 740, 700—that is, an average sodium chloride content of 715.66 mg. (Four showed no cells, one showed 3 lymphocytes per c.mm., and another 2 lymphocytes.)

The fluids from the ten cases of non-tuberculous lesions of the nervous system—other than meningitis—gave the following figures (mg. per 100 c.cm.): 620, 670, 600, 650, 620, 650, 600, 640, 680, 600—that is, an average sodium chloride content of 633 mg. (The cell content varied from 5 to 920 per c.mm., and 100 per cent. lymphocytes were present in all cases except two—namely, the two cases of polio-encephalitis, which showed 80 per cent. and 85 per cent. lymphocytes.)

The fluids from the twenty-six non-tuberculous meningitis cases gave the following figures (mg. per 100 c.cm.): 640, 670, 640, 644, 620, 600, 600, 680, 640, 650, 640, 690, 640, 600, 640, 600, 640, 620, 660, 620, 620, 640, 620, 580, 660, 660—that is, an average sodium chloride content of 632.84 mg.

The case of syphilitic meningitis showed 33 cells per c.mm. (100 per cent. lymphocytes), and the case of aseptic meningitis 2,450 cells per c.mm., 80 per cent. being lymphocytes. In all the others polymorphs predominated, the average percentage being 87.4. The lowest percentage of polymorphs in any case was 60; the highest was 98. The total cell count varied between 54 and 6,000 per c.mm.

TUBERCULOUS FLUIDS—CHLORIDE CONTENT

Of the eighty-four cases of tuberculous meningitis only two had a chloride content exceeding 550 mg. per 100 c.cm. The latter were the two cases which failed to show tubercle bacilli in the fluid as obtained by lumbar puncture, and they call for special comment. One was that of a man aged 45, the other that of a boy aged 11. Both patients suffered from miliary tuberculosis, particularly in the lungs, and eventually developed tuberculous meningitis and died. The findings were confirmed post mortem, and it is of special interest to note that in both cases thickening of the meninges at the base of the brain had given rise to internal hydrocephalus and there was no evidence of extension to the spinal meninges. The complete examination of their fluids were as follows:

Case 1 (man aged 45).—The fluid, bright and clear and of light amber colour, was examined two days before death. The cell count showed 3 per c.mm., all lymphocytes, and the globulin was ++. The sugar content was 85 mg., the protein 200 mg., and the chlorides 640 mg. per 100 c.cm. No organisms seen in stained films.

Case 2 (boy aged 11).—There were two examinations. In the first, on October 10, 1935, the fluid was bright and clear, and light amber in colour. The cell count gave 96 per c.mm., 65 per cent. being lymphocytes. There was no globulin. The sugar content was 45 mg. per 100 c.cm., the proteins 56 mg., and the chlorides 620 mg. A stained film showed no

organisms. The second examination, on October 19, revealed no change in the appearance of the cerebro-spinal fluid, but the cells had fallen to 22 per c.mm., 90 per cent. being lymphocytes. There was no globulin. The sugar content was 40 mg., the proteins 62 mg., and the chlorides 600 mg. per 100 c.cm.. No organisms were observed in a stained film The patient died on October 24.

Chemical examination of the cerebro-spinal fluids containing tubercle bacilli in the eighty-two cases of tuberculous meningitis revealed a chloride content averaging 510.24 mg. per 100 c.cm. The highest chloride content in any field was 550 mg. and the lowest 420 mg. per 100 c.cm. The cell content varied within wide limits—from 20 per c.mm. (100 per cent. lymphocytes) in a bright clear fluid free from clot to 1,952 per c.mm. (96 per cent. lymphocytes) in a cloudy fluid showing a clot of fibrin.

Comments

A differential count of the cerebro-spinal fluid occupies about fifteen minutes and has a certain diagnostic value. In tuberculous meningitis lymphocytes predominate; the lowest percentage in any fluid of the present series (eighty-four cases) was 58, and the average 92. But a high percentage of lymphocytes may be found also in syphilitic meningitis, aseptic meningitis, and a number of lesions of the nervous system other than meningitis, and so is not pathognomonic. In all other forms of meningitis, however, polymorphs greatly predominate; in the twenty-six cases referred to above the lowest percentage of polymorphs was 60 and the highest 98, and the average percentage was 87.4.

Microscopical examination of the centrifuged deposit from a fluid with a chloride content not exceeding 550 mg. per 100 c.cm., if sufficiently prolonged, will always reveal the presence of tubercle bacilli. Only about 2 per cent. of cases of tuberculous meningitis may have a high chloride content (over 600 mg. per 100 c.cm.), and these will fail to show organisms even after two and a quarter hours' search. The finding of tubercle bacilli in the cerebro-spinal fluid of any case of meningitis is of course pathognomonic, but the time necessary for success is often very long, and so a negative result is frequently reported.

Centrifugalization of the fluid and making and staining a film occupy fifteen to twenty-five minutes or more, and the subsequent microscopical examination may entail a prolonged search. In the present series of eighty-four cases the organism was demonstrated in eighty-two (approximately 98 per cent.)—a high proportion of positives—but the time expended on the microscopical examination varied from two minutes to two and a quarter hours. As a rule twenty-five to thirty minutes' searching was necessary, but a longer time was often required, and in at least five cases the search had to be prolonged to two and a quarter hours. Few workers can afford sufficient time for success.

The estimation of the sodium chloride content of the cerebro-spinal fluid takes only fifteen minutes. In eighty-two of the eighty-four cases investigated—that is, approximately 98 per cent.—the sodium chloride content was found greatly reduced, averaging 510.24 mg. per 100 c.cm. The lowest and highest limits were 420 mg. and 550 mg. respectively. In none of the forty-two controls did the sodium chloride content fall below 580 mg. per 100 c.cm., the vast majority having over 600 mg. Technique must be accurate, however, and all precautions must be taken to avoid contamination with extraneous chlorides. With this proviso it may be said that a sodium chloride content of 550 mg. per 100 c.cm. and under is found only in tuberculous meningitis, and is practically pathognomonic of the disease.

Method of Estimating the Sodium Chloride Content

The method adopted in estimating the sodium chloride content of the cerebro-spinal fluid is a modification of that described by Whitehorn (1921). The following is the apparatus required, all of which must be chemically clean:

Two 5 c.cm. microburettes calibrated in 0.02 c.cm.; Grade B, N.P.L.
One 10 c.cm. bulb pipette; Grade B, N.P.L.
Two 2 c.cm. bulb pipettes; Grade B, N.P.L.
Two 1 c.cm. bulb pipettes; Grade B, N.P.L.
One 10 c.cm. graduated pipette; Grade B, N.P.L.
One 50 c.cm. conical flask (pyrex).
One 5 c.cm. measuring cylinder.
One glass funnel, ribbed, 2 inches diameter.
Two test tubes.
One box Whatman's filter papers No. 1, 11 cm. diameter.

The reagents necessary are:

Powdered iron alum, chlorine-free.
Concentrated nitric acid, chlorine-free.
2/3 normal sulphuric acid.
10 per cent. aqueous solution of sodium tungstate.
Distilled water prepared in a pyrex all-glass still.
Standard solution of sodium chloride: 1 c.cm. = 2 mg. NaCl.
Standard solution of silver nitrate: 1 c.cm. = 2 mg. NaCl.
Standard solution of potassium thiocyanate: 1 c.cm. = 2 mg. NaCl.

These three standard solutions are prepared as follows.

Preparation and Standardization of Solutions

Standard Solution of Sodium Chloride.—A stock solution is first prepared by dissolving 10 grammes pure dry sodium chloride in 500 c.cm. of distilled water. Its strength, therefore, is 1 c.cm. = 20 mg. sodium chloride. The standard solution is prepared, as required, by diluting the stock solution with distilled water ten times, so that 1 c.cm. = 2 mg. sodium chloride.

Standard Solution of Silver Nitrate.—Dissolve 5.81 grammes of pure silver nitrate in distilled water and make up the volume to 1,000 c.cm. (1 c.cm. = 2 mg. sodium chloride). Store in amber bottle.

Standard Solution of Potassium Thiocyanate.—Dissolve about 6 grammes of pure potassium thiocyanate in 1,000 c.cm. of distilled water, mix thoroughly, and standardize as follows:

Measure 10 c.cm. of distilled water into a 50 c.cm. flask and add 5 c.cm. of standard silver nitrate solution from a 5 c.cm. microburette and 3 c.cm. of concentrated nitric acid (chlorine-free). Shake, cool under water-tap, and allow to stand for two minutes. Then add about 0.3 gramme of powdered iron alum. Titrate with the potassium thiocyanate solution from a 5 c.cm. microburette until the last trace of silver has been precipitated. This is indicated by the development of a pink colour due to the formation of ferric thiocyanate. Adjust the concentration of the potassium thiocyanate solution until 5 c.cm. corresponds with 5 c.cm. of silver nitrate solution.

The standard solutions having thus been prepared the strength of the standard solution of silver nitrate, in the interests of accuracy, should now be checked as follows:

Measure 5 c.cm. of distilled water into a 50 c.cm. flask and add 5 c.cm. standard sodium chloride solution, 10 c.cm. standard silver nitrate solution, and 3 c.cm. concentrated nitric acid. Shake, cool under water-tap, allow to stand for two minutes, and then add about 0.3 gramme iron alum. (The 5 c.cm. sodium chloride will combine with the 5 c.cm. of silver nitrate and so leave 5 c.cm. of silver nitrate to be titrated.)

Titrate with the potassium thiocyanate standard solution until the definite pink colour first appears. This should require 5 c.cm. potassium thiocyanate if the strength of the silver nitrate solution is correct.

TECHNIQUE OF TEST

(All apparatus must be chemically clean.) The lumbar puncture needle must be sterilized in boiling distilled water, alcohol, or by dry heat. No saline or tap-water should be used. The test tube for collecting the cerebro-spinal fluid must be chemically clean, sterilized by dry heat, and closed with a sterile cork covered with tin-foil (not cotton-wool plug). At least 10 c.cm. of cerebro-spinal fluid is required. The following is the procedure:

(i) Observe appearance of fluid, then shake and pour about 1 c.cm. into a small test tube for estimation of white-cell content.

(ii) Centrifuge remainder for twenty minutes at high speed in a conically bottomed centrifuge tube.

(iii) Remove supernatant fluid—without interfering with any clot present—using a fine-pointed capillary pipette and rubber teat. The top end of the pipette should be guarded with a small plug of cotton-wool which has been previously washed in distilled water, dried, and sterilized. As much supernatant fluid as possible is transferred to a chemically cleaned sterile test tube.

(iv) All the deposit is then transferred by means of the capillary pipette to the centre of a microscope slide and, without having been spread, the drop is dried by gently heating. The conical part of the centrifuge tube is then washed with two or three drops of the supernatant fluid and the washing transferred to the dried drop on the slide. Without spreading, the slide is then dried for ten minutes in the 55° C. incubator, and in this way a highly concentrated film is obtained. Afterwards it is stained in the usual manner by Ziehl-Neelsen's method.

(v) Precipitate the proteins from the supernatant cerebro-spinal fluid obtained in (iii) above by Folin and Wu's method, as follows: Measure 16 c.cm. distilled water into a test tube and add 2 c.cm. of the cerebro-spinal fluid, 1 c.cm. sodium tungstate, and 1 c.cm. 2/3 normal sulphuric acid; mix gently, allow to stand for five minutes, then filter into another test tube, using a funnel and Whatman's No. 1 filter paper. Estimate the sodium chloride content of the filtrate as follows:

(vi) With 10 c.cm. bulb pipette transfer 10 c.cm. of the filtrate to a 50 c.cm. conical flask and add 5 c.cm. standard silver nitrate solution (using burette) and 3 c.cm. concentrated nitric acid.

Shake, cool under water-tap, allow to stand for two minutes. Add about 0.3 gramme iron alum, then titrate with standard potassium thiocyanate solution from 5 c.cm. burette until definite pink colour is obtained.

The formula upon which the calculation is made is:

(5 c.cm. minus volume of potassium thiocyanate used) $\times 200$ = No. of mg. sodium chloride in 100 c.cm. cerebro-spinal fluid.

Summary

1. Diminution of the sodium chloride content of the cerebro-spinal fluid—practically a constant feature of all inflammatory conditions of the cerebro-spinal nervous system—is greatest in tuberculous meningitis.

2. As different observers have given very divergent figures for this diminution a reinvestigation of the question has been undertaken and the results are here set out.

3. The chloride content of the cerebro-spinal fluid of 126 patients was investigated. Eighty-four suffered from tuberculous meningitis, and forty-two were non-tuberculous and served as controls. None of the controls showed a sodium chloride content below 580 mg. per 100 c.cm., the vast majority having over 600 mg.

4. A sodium chloride content of 550 mg. per 100 c.cm. and under was found only in tuberculous meningitis, and may be considered practically pathognomonic of this disease. Microscopical examination of such a fluid, if sufficiently prolonged, will always reveal tubercle bacilli.

5. Only about 2 per cent. of cases of tuberculous meningitis may show a high chloride content (over 600 mg. per 100 c.cm.), and these will fail to reveal organisms even after two and a quarters hours' search.

6. The technique of the test—a modification of that described by Whitehorn—is given in detail, and its performance occupies fifteen minutes. It is of the utmost importance to exclude any extraneous source of chloride contamination, and accurate technique is essential.

EFFECT OF HEAT AND ULTRA-VIOLET RADIATION ON ISO-AGGLUTININS IN DRIED BLOOD STAINS

BY

A. I. KAYSSI

AND

W. GILBERT MILLAR, M.B., Ch.B.

(From the Department of Forensic Medicine, University of Edinburgh)

The primary object of the present study was to see to what extent adverse conditions would affect the grouping of bloods by means of dried stains kept in circumstances similar to those likely to be met with in ordinary medico-legal practice. For this we chose to deal with the iso-agglutinins as being more labile than the agglutinogens, and to expose the stains to dry heat and to ultra-violet radiation—these being factors likely to occur in practice, particularly in the Tropics—the influence of which on the stain might be important.

Method

Blood was collected from eighteen volunteers of both sexes and allowed to dry at room temperature on glass slides, on scraps of leather, and soaked up in ordinary plain surgical gauze. The material was kept in unsealed envelopes lying on the laboratory bench, conditions being thus pretty much what might obtain in the case of a stain met with in practical medico-legal work. The agglutinins of the stains were tested against cells of Type A, Type B, and two specimens of Type O, designated O1 and O2 respectively. The cells were collected in citrated saline, washed once, and suspended in 0.85 per cent. saline in a 3 per cent. suspension. The bulk of the tests were carried out on blood dried on slides, but no differences were detected in stains on leather or gauze. In each case a fragment of stain was detached and placed on a slide, a small quantity of dilute cell suspension added, and a cover-glass applied. After five minutes the cover was very gently agitated and the slide examined for agglutination, examination being again made at the end of a further five minutes. Brisk stirring is to be avoided, as it greatly encourages rouleau formation. The blood group of the donor had been determined at the time of collection of the blood stain by the usual slide method.

Results

All specimens were examined ten days after collection and without any further treatment. In each case the group was determined without difficulty and correctly, the worker reading the result being of course kept in ignorance of the already determined group. The results are tabulated in Table I.

One batch of six stains was heated to 64° C. for one hour in an electric drying oven and then submitted to grouping as before. Little, if any, diminution in agglutinin content was noticed, no difficulty being experienced in obtaining a correct group in each case at the first attempt.

Portions of all stains were then heated to 100° C. for one hour in the drying oven and typing done as before. The results are shown in Table III.

A further typing was carried out on a group of stains similarly treated six days after, the results of which experiment are listed in Table IV.

Difficulty was experienced in diagnosing the group of some of the stains, mainly in those cases where too brisk stirring had been employed. In all cases, so far as could be judged, the strength of the agglutinins was considerably diminished, and larger portions of the stains had to be taken to get agglutination.

Portions of seven stains (two from each of Groups A, B, and O, and one AB specimen) were placed in small glass staining blocks and exposed for one hour to ultra-violet light at fifteen inches from a Hanovia quartz analytical lamp. Care was taken to see that the portions of dried clot did not overlap and screen

each other from the rays. The stains were afterwards grouped, and so far as could be observed the radiation produced no effect. A further experiment was therefore carried out. Portions of all stains were taken three weeks after bleeding and exposed in a similar fashion for three hours without apparent effect.

The effect of heat combined with ultra-violet light was investigated in a further group of six stains by exposing for one hour at fifteen inches from the quartz lamp stains which had previously been subjected to dry heat for one hour at 100° C. The results are contained in Table VI.

TABLE V.—*Stains Exposed Three Hours to Ultra-violet Light*

Group already Determined	No. of Specimens	Agglutination of Cells				Group Diagnosed
		A	B	O1	O2

A	13	–	+	–	–	A
A	9	–	+	–	–	A
O	4	+	+	–	–	O

TABLE VI.—*Stains Heated One Hour at 100° C. and then Exposed One Hour to Ultra-violet Light*

Group already Determined	No. of Specimens	Agglutination of Cells				Group Diagnosed
		A	B	O1	O2	
O	10	+	+	–	–	O
AB	18	–	–	–	–	AB
O	3	+	+	–	–	O
A	1	–	+	–	–	A
A	2	?+	+	–	–	?O
O	7	+	+	–	–	O

It will be seen that in most cases radiation has produced no further effect on the agglutination except in Specimen 2, which shows a doubtful positive agglutination of A cells. The main thing to be noticed is the absence of any trouble from rouleau formation.

Discussion

It is evident that drying at room temperature and storage for ten days in ordinary conditions does not seriously affect the readiness with which stains can be grouped by their agglutinins. These also appear to resist dry heat for one hour at 64° C. without serious impairment, but a similar exposure to 100° C. does cause some loss of power. A further point is the apparent increase of the factors tending to regular rouleau formation. This may be apparent only, and due entirely to the extra concentration necessary to produce agglutination; but our feeling is that this is not the whole explanation, since we noticed the appearance of this phenomenon when the concentration of the stain was not greatly increased. It is curious also that subsequent irradiation seems to diminish rouleau formation almost to vanishing-point. To investigate these facts further is not possible by the relatively crude methods we have used in the present series of experiments.

Conclusions

1. In agreement with generally accepted views no difficulty has been experienced in accurately diagnosing the group of a blood by the agglutinins present in a dried stain. Moreover, no difficulty ensues after exposing the stains to dry heat at 64° C.

2. Dry heat at 100° C. diminishes the strength of the agglutinin factor to a considerable extent, but does not usually abolish it completely; and this temperature seems to have some influence on the appearance of regular rouleau formation.

3. Ultra-violet radiation under the above-described conditions produces no obvious effect on the agglutinins. On the other hand, it does seem to have a certain influence in diminishing the formation of regular rouleaux.

4. It seems unlikely that ordinary blood stains would lose much of their agglutinin content if kept dry, even if they were exposed to strong sunlight and fairly high temperatures.

BIBLIOGRAPHY

The literature on the subject is so extensive that no attempt is made to cite it here.

So far our search has not shown any work on the agglutinin factors in dried stains on the lines of the present investigation. A good review of the general technique of blood grouping is to be found in a paper by J. C. Thomas (*Medico-Legal and Criminological Review*, 1937, 5, 54).

The National Institute of Industrial Psychology (Aldwych House, W.C.2) has just published the July–August issue of *The Human Factor*, price 2s. 6d. The first article, by Mr. H. D. Henderson, deals with the displacement of labour by machinery. Mr. T. G. Rose, recently appointed general director of the Institute, has written an article on clearer business vision, in which he stresses the need for good will in any industrial concern. Dr. O. A. Oeser of St. Andrews University deals with the complex social and psychological factors which may determine the choice of a career. The Institute is now developing an advisory service to educational authorities on the design and provision of equipment, and on methods of heating, lighting, and ventilation in schools. Results of various investigations are detailed in an article on school buildings.

Clinical Memoranda

Neuritic Symptoms following Injection of Gold Salts

Graham Lescher (1936) has recently described a case of polyneuritis following treatment by gold salts and has commented on the extreme rarity of this complication. In our experience, obtained mainly in the treatment of skin diseases, lupus erythematosus, psoriasis, lupus vulgaris, sarcoids, etc., over a number of years, neuritic complications have not been seen.

The common gold reactions—exfoliative dermatitis, eczematous reactions, stomatitis—cannot be foreseen in any individual case, but as Hartfall and Garland (1936) have indicated, are less likely to occur with small doses of gold. However, there is interest in the speculation that the neuritic type of reaction may be anticipated and be preventable.

CASE REPORT

Our patient was a lady of 57 years who complained of burning in the soles of the feet for a year. Several years ago she had had pain and swelling of the small joints of the hands. The skin of the feet, particularly at the pressure points, was red, hyperkeratotic, and showed numerous telangiectases. On the lower lip, spreading beyond the red margin, was a red defined area, finely scaling. The tip of the tongue was red and smooth. At the angles of the mouth there was some dry fissuring. On the right of the scalp was a bald patch with slight atrophy. The appearance of the lower lip and of the feet suggested the diagnosis of lupus erythematosus, and the bald patch on the scalp was thought to represent the site of a healed area of this disease. The patient gave no dyspeptic history, but a test meal showed no free or combined acid during the two hours following the meal. The blood count (Dr. Knott) gave 100 per cent. haemoglobin, 5¼ million red blood cells, and 8,900 white blood cells, with a normal differential count. The blood uric acid (Dr. Ryffel) was normal (3.2 mg. per 100 c.cm.). The following doses of gold were prescribed: October 15, 1936, solganol B 0.05 gramme; October 22, solganol B 0.1 gramme; October 29, solganol B 0.1 gramme (on this date she was given 20 grains each of sodium bicarbonate and potassium citrate before meals, and 40 minims of dilute hydrochloric acid in water with meals); November 6, solganol B 0.1 gramme. Three days after the last dose of gold the temperature rose to 102°, and remained 99° to 100° in the morning and 102° to 104° in the evening for thirteen days. There was severe pain in the limbs and the back, with sweating. The throat was injected. At first she was thought to have contracted influenza. There was superficial tenderness to touch in the limbs, particularly severe around the upper abdomen and ribs. The knee-jerks were normal and the plantar reflexes were not obtained.

There was increasing restlessness at night, which was not relieved by full doses of Dover's powder, allonal, veganin, and chloralamide. The temperature gradually subsided after a further three weeks. The patient was comfortable during the day, but the superficial tenderness and pins-and-needles with severe restlessness returned at night, together with a rise of temperature. Dragging of the feet was noticed when she got out of bed. The temperature and symptoms subsided gradually during the next month.

Lescher's case showed some points of similarity with the above. Thus, the patient was a lady of middle age, there was some glossitis with achlorhydria, and a normal blood count. In our case, however, only 0.35 gramme of solganol B had been given against 1.56 grammes of myocrisin; but, as Lescher states, "nervous complications can occur soon after the first injection of the salt, or more commonly near the end of the first or subsequent courses." The restlessness, insomnia, and desire to walk about at night have been observed by others.

Whether the febrile reaction seen was due to the direct toxic action of the gold is a matter for discussion. The extreme rarity of the complication would suggest the possibility of another factor, and in this connexion we would refer, as Lescher has done, to Douthwaite's (1936) cases of gastrogenous polyneuritis, in which the only constant finding was an achlorhydria associated sometimes with anaemia. The achlorhydria and glossitis were present in the two cases discussed above, and it appears possible that a latent polyneuritis was activated by the gold.

It seems to us a counsel of perfection to give a test meal and take a blood count in all cases of skin disease in which gold treatment is proposed and in some cases may be impracticable. If in spite of the finding of an achlorhydria it is considered desirable to give gold, preliminary medication with hydrochloric acid, glycerin of pepsin, and vitamin B, as Douthwaite suggests, might improve the health of the peripheral nerves and prevent the appearance of this distressing complication.

Carcinoma of Bronchus in a Boy of 19

It may be of interest to report a case of carcinoma of the bronchus in a boy of 19 resembling in many ways the case described by Dr. J. Gordon Hailwood in his interesting paper in the *Journal* of March 20 (p. 606).

H. E. S., transport driver's mate, aged 19 years 11 months, was admitted to this sanatorium in March, 1935, with a history of cough and scanty sputum for the past ten weeks, diagnosed as "bronchitis"; two weeks prior to admission his sputum was blood-stained. He also complained of pain and stiffness of the hips and knees, present for about two weeks.

On admission there was a large right-sided pleural effusion with gross displacement of the heart and trachea to the other side. The opposite lung was congestive in appearance. Sputum 1 oz., frothy and blood-stained, tubercle-negative; temperature 100° F., pulse 120. On aspiration the fluid was uniformly haemorrhagic, and 42 oz. was slowly aspirated to bring the heart back to its normal position. A few days later the effusion was replaced by air, 80 oz. of blood-stained effusion being removed. A radiograph at this stage showed a large mass occupying the right lower lobe area, and the mediastinal shadow was double width. The pain in the legs persisted and progressed, and within ten days of admission he had developed a complete flaccid paraplegia with sphincter incontinence. The Wassermann reaction was negative. The diagnosis made was neoplasm of the lung with secondary mediastinal glands and secondary deposit in the spine. He was discharged to a general hospital, where he died four and a half months later.

A necropsy revealed a tumour the size of a small orange apparently arising from the main right bronchus; the growth had extended and had infiltrated the walls of the right auricle and ventricle. The mediastinal glands were involved, secondary nodules were present in the liver, and there was neoplastic destruction of two of the lower dorsal vertebral bodies. On section the tumour was found to be an oat-celled carcinoma.

Reviews

INJURY IN RELATION TO DISEASE

Trauma and Disease. Edited by Leopold Brahdy, B.S., M.D., and Samuel Kahn, B.S., M.D. (*Pp. 613*; illustrated. 35s. net.) London: H. Kimpton. 1937.

Textbooks of medicine mention injury as a factor in the aetiology of a great many diseased conditions, but the evidence of such a relation is often most inadequate, amounting to little more than the fallacious argument, *Post hoc, ergo propter hoc*—"Toads appear after rain, therefore it has rained toads." Drs. Brahdy and Kahn have set out in this book to show exactly in what circumstances and to what extent injury may cause or aggravate disease processes; these editors have been assisted by twenty-two colleagues, and the result of their labours is a most valuable book. The postulates are clearly expressed upon which an opinion may be based as to whether a given pathological condition is a result of trauma. The work of previous investigators is subjected to a critical review, and a great deal of original observation is recorded. The great war provided an immense amount of material for research in this matter, and some interesting deductions are made. It was found, for example, that the incidence of organic disease of the central nervous system was not appreciably greater among those exposed to war hazards than among persons not so exposed. The possibility of tumours being due to injury is thoroughly discussed, and the conclusion is reached that "there is no reasonable evidence of any relationship between a single injury and the production of a cancer," exception being made in the case of sarcoma arising in the site of a fracture, and malignant disease supervening in a scar. There is experimental evidence to show that injury is just as likely to set up retrogressive changes in a tumour as to accelerate its growth. Injury is so common (in 1933 there were recorded over eight million disabling accidents in the United States, and Vernon estimates that the annual total is much higher than this) that the factor of coincidence is very important. The authors assert that "trauma has not been proved to have any significant tendency to cause or aggravate tumours of the brain," and figures are quoted showing that although a history of head injury was elicited in 13 per cent. of a series of 431 cases of cerebral glioma, a similar history was obtained among 35.5 per cent. of a control group of 200 normal persons.

There is an excellent chapter on trauma and diabetes mellitus, written by Dr. Joslin, with the co-operation of Drs. Root and Marble. The hereditary factor in this disease is stated to be of very great importance, but is often insufficiently appreciated owing to lack of adequate inquiry. Thus a woman developed diabetes at the age of 20, when she quoted only one relative as suffering from this disease; twenty-two years later it was established that eighteen of her relatives were diabetic, including her mother and grandmother. Although a single direct injury to the pancreas can scarcely ever set up diabetes (unless nine-tenths of the gland is destroyed—a state of things almost certain to be quickly fatal), yet the disease may appear in a susceptible person—that is, one with a diabetic heredity—as a result of overfeeding and lack of exercise consequent upon an injury. One war veteran in America actually established his right to a pension in respect of diabetes, brought on by "exposure to food" in a camp at Hoboken, where he put on much weight! The incidence of diabetes among the American troops in France was lower than among those who did not proceed over-seas; and out of 12,498 wounded men there were only three recorded cases of diabetes, two of which were seen by the author, who found no reason to attribute the disease to war service; his conclusion was that neither the organic nor the psychical traumata of war had any appreciable importance as causes of diabetes.

The general plan in this book is to give a short, systematic account of a pathological condition, then case-histories showing how such a condition may follow injury, and finally a commentary explaining the relation of the disease to the injury. No attempt is made to deal with such obvious sequences as fractures due to single accidents, perforation of viscera by foreign bodies, or ordinary infections of damaged tissue. Other omissions are less easily accounted for. Thus there is no discussion of the problem of traumatic hernia, or of detachment of the retina after blows on the head. "Juxta-epiphyseal strain" is not mentioned as a predisposing factor in osteomyelitis; indeed, the opinion is expressed that trauma plays "an extremely rare role in the aetiology" of this disease, except in cases of compound fracture.

The book is well printed and has an adequate index and very full bibliographical references, and should prove to be of great value to those who have to advise in cases of claims for personal injury in which the relation of the alleged injury to the present condition is not clear.

HYGIENE FOR MEDICAL STUDENTS

Handbook of Hygiene. For Students and Practitioners of Medicine. By Joseph W. Bigger, M.D., Sc.D., F.R.C.P.I., D.P.H. (Pp. 406; 16 figures. 10s. 6d.) London: Baillière, Tindall and Cox. 1937.

Works on hygiene published lately in this country have shown a tendency to arrange themselves into two main groups: first, the smaller books, which seek to aid the medical or other student in the revision of his previous knowledge, and, secondly, the larger textbooks, addressed to candidates for a public health diploma, which include a wider field. But neither group meets the genuine need of the student of medicine. For his own study of hygiene he requires something between.

A work which may claim to fill this gap in a very adequate manner now appears from the pen of Professor Bigger of Dublin. It is, as the author states in his preface, specially intended for medical students. After an introductory note on vital statistics the communicable diseases are presented, as is proper, in some detail. The view is expressed that the student of medicine derives little profit from courses of instruction in vaccination as usually conducted. On disinfection the author says, "With the exception of small-pox, room disinfection is only necessary in the case of diseases conveyed by insects." He deprecates alarmist discussion of the so-called cancer menace. "More nonsense," he says, "has been spoken and written about the cause of cancer than about almost any other subject." That his outlook is not limited to the narrow seas is shown by his reference to the mottling of the dental enamel occasioned in North America and elsewhere by fluorine-charged waters. One of the many good points which he makes is that "while ventilation and heating must be considered together, they must never be effected together."

Where opinions differ the author is fair to both sides, but he never fails to state his own view, which is a substantial merit in a work of this kind. He writes with candour and elegance, and from time to time makes happy use of a lively phrase to vary his graver discourse.

For example, speaking of air temperature, he says, "It is doubtful which of the two feels more uncomfortable—an American in an English house or an Englishman in an American house during the winter."

The book covers its field well. In addition to the usual topics it includes a section on war gases. It should meet the requirements of those to whom it is addressed. In his preface the author expresses the hope that his students will not sell their copies when their examinations have been passed. We do not think they will.

LIFE IN THE R.A.M.C.

Soldiering With a Stethoscope. By Colonel N. J. C. Rutherford, D.S.O., M.B. (Pp. 288; illustrated. 12s. 6d. net.) London: Stanley Paul and Co. 1937.

This book, as its name implies, is a chronicle of life in the R.A.M.C. Colonel N. J. C. Rutherford joined this corps in 1898, and a year later he was on active service in South Africa, his varied experiences in the campaign including a term as medical officer of a Colonial mounted infantry unit—Nesbitt's Horse. In 1908 he served for a short time in Sierra Leone. During the great war he saw much active service in France and on the Salonika front, followed by a period in Constantinople during the troubled years which succeeded the armistice. In 1924 he was stationed in India, seeing that country for the first time at the age of 50, and finally, on his retirement from the active list, he held the post of resident medical officer at the Tower of London for four years until 1933.

There is not a dull page in this book. Blessed evidently with an equable temperament Colonel Rutherford takes the rough with the smooth and never fails to see the humorous side of life. The chapters on the war of 1914–18 are especially good. The author describes the dashing escape of a German Uhlan from some British headquarters in the Hotel de Ville at Steenwerck: "It was a real romantic effort and I hope he got away safely." This comment is from the colonel's diary, written at the time, and shows the consistent freedom from hate and rancour which appears to be a pleasant feature of his character. This book reveals what an enjoyable, useful, and interesting life may be spent in the R.A.M.C., and many readers will probably regret that their career has lain in less adventurous paths.

PROBLEMS OF GROWING CHILDREN

The Growing Child and its Problems. Edited by Emanuel Miller, M.A., M.R.C.S., L.R.C.P., D.P.M. (Pp. 231. 6s. net.) London: Kegan Paul and Co. 1937.

This is a volume of useful essays by seven well-known writers on child psychology, including the editor, on the problems presented by the mental growth of children from 5 years of age to the close of adolescence. They attempt to describe the sort of mild disorders which show that a child is troubled or maladjusted, and how best to meet these difficulties and clear the path by which the child may enter adult life with a reasonable prospect of success. Miss Gwen Chesters writes a practical article on play therapy and the use of water, sand, dough, and such simple materials in straightening out a child's mind and making it intelligible to himself and his guides. Miss Constance Simmins explains education, guidance, intelligence-testing, and the art of matching a child's schooling with his abilities and tastes. The remaining writers are medical, and Dr. Laura Hutton deals with the adolescent girl and the problems bound up with puberty and its disturbance of the endocrine balance. Personality deviations in children are considered by Dr. Clifford Allen. Dr. Paterson Brown, in an essay on habits, traces the origin of most of the excessive practices which give trouble in childhood, and advises the parent or teacher to be tolerant of habits if he would be saved from worse disasters. In a study of neurosis in school children Dr. C. L. C. Burns points out the contributory factors in the parents and gives sound advice for treatment.

The last essay in the book is by the editor, on problems of the growing child; Dr. Miller writes in his usual effective manner on the basis of his great experience. The several papers are, on the whole, conspicuous for the practical attitude which their writers adopt towards these difficult subjects.

GASTROPHOTOGRAPHY

Atlas der Gastrophotographie. By M. J. Heilpern, O. Porges, and H. Hofmann. (Pp. 29; 38 plates, 7 figures. M. 10; geb., M. 12.) Leipzig and Vienna: F. Deuticke. 1936.

The difficulties in diagnosis of gastric diseases have driven practitioners to seek methods of securing information about the state of the mucous membrane of the stomach if possible by means that cause no inconvenience or risk to the patient. The earlier gastroscopic apparatus, rigid and of a large enough diameter to obtain useful views, was by no means free from danger, and many were led to try methods of obtaining photographs of the lining of the stomach. The difficulties were those principally of illumination and of sighting to obtain views of lesions thought to be present. Professor Porges and his collaborators have invented a gastrophotographic apparatus which they have modified over the years, and by means of it they can obtain very fair photographs of the gastric mucous membrane. In a short book they have brought together the results of their work. Twenty pages are given to the description of their improved apparatus and the technique to be adopted in using it, and the remainder of the book is made up of series of photographs of the gastric mucous membrane in all sorts of states—normal, inflamed, ulcerated, and malignant. There are many fallacies in the interpretation of the pictures obtained; the appearance of mucus or blood must be recognized, normal folds of the gastric lining have to be differentiated from hypertrophic or atrophic states and the edges of ulcers or the projections of cancer.

The photographs are clearly reproduced and their meaning is discussed in the text, and readers will find in the book a very useful guide to a highly specialized and difficult technique. And those who have worked at the subject and recognized its limitations will still feel that a better and more satisfactory diagnosis may be made by confirming the serial pictures, obtained by careful technique with *x*-ray and barium meals during the filling and emptying stages of the stomach, with gastroscopy by means of the convenient flexible modern gastroscope the use of which is fraught with little or no risk to the patient.

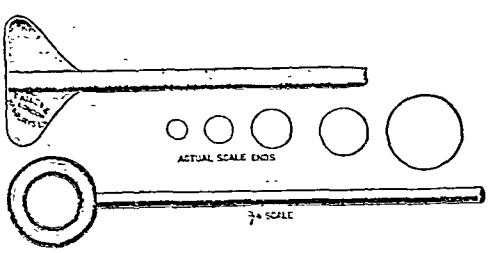
Notes on Books

The Soul of the White Ant, by the late EUGENE N. MARAIS (Methuen, 7s. 6d.) is a remarkable study in natural history, comparable to the work of Henri Fabre. The term "white ant," as the author admits, is a misnomer, for the book deals with the life of termites. The author puts forward the theory that the organic unity of the termitary may be compared with the human body, the position of the queen being analogous to that of the human brain. Maeterlinck, in his *Life of the White Ant*, maintained the same thesis, but Miss Winifred de Kok,

who has translated the present volume from the original Afrikaans, brings evidence to establish Marais's claim to priority. While the greater part of the book is devoted to the termitary and its inmates (or constituent parts), the author digresses in one most interesting chapter entitled "What is the Psyche?" to baboons. As a result of long and close acquaintance with these animals he states that the difference between the psyche of the lowest baboon and of the highest mammal below the primates is far greater than that between the baboon and man. He regards the psyche of man and of the baboon as the same in quality, differing only in quantity. This book is a record of painstaking observations and the deductions drawn from them by an independent, logical, and analytical mind. Any reader to whom the subject appeals will find it of absorbing interest.

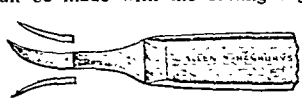
The Transactions of the American Gynecological Society for 1936 (Volume 61) have been issued under the editorship of Dr. OTTO H. SCHWARZ by the C. V. Mosby Company of St. Louis. The papers contributed to this society during the year are followed by obituary notices of six American gynaecologists, and of Sir Kedarnath Das of Calcutta and Professor William Blair-Bell of Liverpool.

No. 17 of the Individual Psychology Medical Pamphlets includes the *Parent–Child Relation*, and other papers read before the Medical Society of Individual Psychology, London. It is published by the C. W. Daniel Company, Ltd., at 2s. 6d.



The Union Press of Bombay has printed in pamphlet form a paper on *Assessment of Risks in Life Assurance Practice*, contributed by Dr. JEHANGIR J. CURSETJI of Bombay to the third Indian Insurance Conference, held in Calcutta on March 7, 1937.

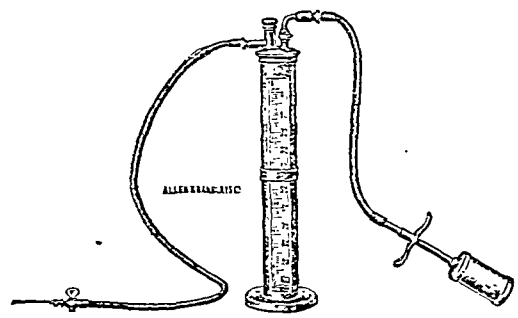
Preparations and Appliances



INSTRUMENTS FOR PLANTAR WARTS

Dr. F. A. E. SILCOCK (honorary dermatologist, Leicester Royal Infirmary and City General Hospital, Leicester), writes: Having recently had several cases of plantar warts to deal with by surgical excision, I got Messrs. Allen and Hanburys Ltd. to make to my design the following instruments, which have proved very useful.

1. Several punches, consisting of various sized circular steel cylinders with a sharp bevelled cutting edge. These are for punching out the warts, using a size slightly bigger than the actual wart to be removed.



2. A small-bladed scalpel, with the blade curved on the flat. This blade can be made with the cutting edge facing either

right or left. These are handy for either removing the warts by undercutting them or to free the base of the piece of tissue punched out as above.

3. An apparatus for injecting solutions into the skin or subcutaneous tissues under pressure. It can be used for various solutions or for injecting local anaesthetics. The principle of this is similar to that of a soda-water siphon, only the pressure is obtained by means of a small removable external force pump which can be worked with one hand. It consists of a graduated glass cylinder inserted in a metal frame, resting on a rubber base, with a screw-down top provided with two metal connexions leading, one to the pump and having a turn-off tap, the other by means of a short

length of metal tubing from the solution in the cylinder, provided with a fine screw-down release valve, and which can be connected with a length of rubber tubing to the injecting needle. There is also a small turn-off tap at the distal end of this rubber tubing, on to which the needle is fitted. In order that oily or thicker solutions may be used, if required, larger bored metal tubing can be substituted in place of the finer one leading from the solution in the glass cylinder by screwing them on instead. All parts of the apparatus are readily taken down for cleaning and sterilization, and with the exception of the glass cylinder are rustless and unbreakable. If one wants to estimate the exact pressure it can be done by connecting a pressure gauge in place of the pump, but in actual practice I have not found this necessary, as one can be guided by the rate of flow of the fluid, etc. An obvious advantage of this instrument is that one can keep "on tap" large quantities of various solutions, ready to inject, with the minimum of preparation when required. Being of fairly stout construction it should be less liable to be broken than the average glass syringe.

NEW VALVE AMPLIFIER HEARING AID

The technical laboratories of Allen and Hanbury's Acoustic Department have produced a new valve amplifier hearing aid. It appears in two patterns, one working from a two-volt accumulator and dry battery, employing two stages of amplification, and the other with larger capacity batteries and using three valves, giving increased output. The smaller model gives twenty-five hours' use before the accumulator needs recharging, and the dry battery has a life of about three months. The instruments have a wide frequency range, giving effective amplification over 50 to 6,000 cycles per second. Very little background noise is experienced, and for cases in which the slightest background noise may be intolerable a piezo-electric crystal microphone, entirely free from "background," is available at a small additional cost. The user has a choice of four types of air or bone conduction earpieces. An important feature of the instrument is the standardization of automatic volume control, ensuring the maintenance of a comfortable level, with non-registration in the instrument of loud noises in the immediate vicinity. The construction and performance seem to be admirable; the maintenance cost is low—only a few pence per week—and a comprehensive service is guaranteed. The smaller model is carried in a leather case rather like a small camera, to which a shoulder sling can be added. The other model, a more powerful instrument, is carried in a black hide brief case, but being very flat it is no more incommodious than an ordinary handbag. The cost of the models is sixteen and eighteen guineas respectively, in each case including a spare accumulator.

Nova et Vetera

THE SCOTTISH TRADITION IN SURGERY

Sir David Wilkie delivered an address on the Scottish tradition in surgery to the Caledonian Society of London on February 11.

Sir David recalled that it was in London that John Hunter started this Scottish tradition. When some ninety years before the founding of your society, he said, the uncouth West Country lad came up from East Kilbride to London to study anatomy with his learned brother William an epoch in surgery began—from being little more than a craft it was destined to become a science. Hunter, first by his intimate study of anatomy, then by his study of comparative anatomy and biology, by bringing his remarkable powers of observation to bear on disease and founding what we now term surgical pathology, and finally by introducing into the solution of surgical problems the experimental method, laid the foundation for all progress in surgery since his day. He was one of the three greatest surgeons of all time and a worthy founder of the Scottish tradition in surgery. His breadth of view in searching the whole field of nature for the secrets of bodily form and function and their disorders, his rugged honesty, his insatiable curiosity and untiring industry set a standard never since equalled, but forming a constant stimulus and inspiration to all surgeons.

When Jenner, the discoverer of vaccination, debating in his mind the possibility of immunizing human beings by giving them cow-pox, wrote to Hunter for advice he got the laconic and characteristic reply: "Don't think; try it."

Scottish Surgery After Hunter

It is perhaps not without significance to note that at the time of the foundation of your society Scottish surgery stood in higher repute than it ever since has done. In that year Sir Charles Bell returned to Edinburgh to the chair of surgery after a distinguished career in London. Known all over Europe for his researches in anatomy and physiology, he was as distinguished a scientist as he was a gifted artist.

His brother, John Bell, had died some years before, but his influence as a teacher and a surgeon was still evident in the practice of his pupils. One of them, Ephraim McDowell, way out in Danville, Kentucky, had successfully performed the first abdominal operation and generously given the credit to the teaching of John Bell. Lizars followed up McDowell's work in Edinburgh, and was the first ovariotomist in this country.

Syme, one of the greatest surgeons of all time and the father-in-law of Lister, held the chair of clinical surgery and was the leading teacher of the day. It has been said of him that he "never wasted a word or a drop of ink or a drop of blood." To this day the operations which he devised are practised and his principles of teaching are observed.

Just a year before, Syme's colleague, Liston, had gone from Edinburgh to London, where he was to become the leading surgeon of the day. A man of magnificent physique, standing 6 ft. 2 in., he was the greatest exponent of the rapid surgery of pre-anaesthetic days. The students, with their watches in their hands, timed his operations in seconds—amputation through the thigh, 1 minute 15 seconds; removal of a stone from the bladder, 2 minutes 5 seconds. Strangely enough he was the first surgeon in this country to use a general anaesthetic—ether—the year before Simpson first used chloroform in Edinburgh.

When Liston left Edinburgh his place was taken by a surgeon, Fergusson by name, a skilled anatomist and teacher, who four years later went to London, where he justly acquired a commanding reputation as a surgeon and teacher and the greatest exponent of conservative surgery in the country. Sir William Fergusson became Serjeant-Surgeon to Queen Victoria and the leading surgeon of his day.

This remarkable group of men all had this in common—they had all been teachers of anatomy in the famous classrooms of Barclay and of Robert Knox, they had the lion's heart and the lady's hand required for major surgery, especially in pre-anaesthetic days, and all their work was distinguished by sound judgement and by a wise conservatism.

Lister in Scotland

If anaesthesia was first used by Scottish surgeons in this country the still greater advance—antisepsis—was evolved by an Englishman, Lister, working in two Scottish universities. Attracted to Edinburgh by Syme's reputation, Lister became a devoted disciple of this great surgeon and found the atmosphere which favoured the germination of the ideas which were already stirring in his mind.

It was while professor in Glasgow that Lister carried out the crucial tests of his antiseptic system, and when he returned to Edinburgh to fill the chair vacated by Syme it remained only to convince others of the great truth he had laid bare. Returning to enthusiastic students and to visiting surgeons from all over the world, this Edinburgh period was the happiest and most fruitful in his life. Later in London he met with opposition and, still worse, indifference, and often sighed for the generous and open-minded enthusiasm of the crowded classrooms he had left. No one followed the Hunterian tradition more consistently than Lister, who, by bringing the scientific methods of the laboratory to bear on a practical surgical problem, changed the whole face of surgery and for all time made it safe.

The Tradition in Modern Times

Coming still nearer to the present we find the tradition of careful observation and logical deduction leading to rational and successful treatment exemplified in the work of Macewen of Glasgow on the surgery of the brain and of the chest, pioneer work which has stood the test of time. In Aberdeen Ogston maintained the reputation of Scottish surgery for enterprise, combined with soundness, and of Scottish teaching for clarity and candour. Meanwhile in London Watson Cheyne promoted Listerian practice and Scottish teaching methods, and later Thomson-Walker handed on the torch.

In Edinburgh Caird and Stiles raised high again the good name of Scottish surgery, and by their habits of travelling far and wide kept in the forefront of an ever-moving science. That Edinburgh should have again become a Mecca for surgeons from the Dominions and America is largely due to the brilliance of these two men as surgeons and as teachers.

The opportunity for research and for advance in knowledge which surgery now offers to the surgeon and the benefits which result from a correlation of clinical and experimental work were long in being appreciated in this country. It is to the credit of Scottish surgery that the first Department of Experimental Surgery in the Empire was opened in Edinburgh twelve years ago, an example followed in Montreal and London. That young surgeons should have the training in the careful observation and the controlled experiment which the experimental laboratory provides is one of the most important factors in making for advance in medicine, and in promoting this Scotland has led the way.

As in other fields, so in surgery, the Scot owes much to his primary education and to following out the principle that only on a sound foundation of the basic sciences,—anatomy, physiology, and pathology—can a noble edifice for surgery be built. The habit of travel brings enlightenment, and with Scottish surgeons it has been a creed. The reputation for care and for stability, for common sense and blunt honesty, has made the opinion of the Scottish consultant proverbially sound. The young Scottish surgeon has indeed a noble heritage.

SATURDAY JULY 17 1937

CHEAP MILK FOR MOTHERS AND CHILDREN

A "positive milk policy" is being urged upon the Government by the Children's Minimum Council, a body of which Sir Frederick Gowland Hopkins is president and which has the support of twenty-six national organizations concerned with maternity and child welfare. The Council has submitted a plan to the Ministry of Health for the provision of cheap milk for mothers and children under school age. Some recent investigations have shown that the consumption of milk in working-class households is far below the amount regarded as desirable, that consumption falls with falling household income and number of children in the family, and that many children get little or no fresh milk. The report of the Advisory Committee on Nutrition, published in April last,[1] recommended from one to two pints a day for children, two pints for nursing and expectant mothers, and half a pint for other adults; but the Council points out that at present prices this would mean for a family consisting of three children, a mother again pregnant, and a father a weekly milk bill of 13s. 3d.—an impossible expenditure for a working-class family with dependent children. Last year a survey was made of 587 households in Oxford, taken at random and not confined to the working class. In the families where there were no children the average weekly consumption of milk per head was 4.60 pints, and steadily diminished with the number of children until, with six children or more in the family, it became 1.85 pints. In 1,000 "welfare" families in the county of Durham it has been found that the average amount of fresh milk purchased falls from 0.7 pint a week per head for families of three persons to 0.4 pint for families of five. No doubt distaste, prejudice, and indifference contribute to the low consumption of milk, but the full benefit of educational propaganda cannot be effective in the classes where consumption is lowest until milk is offered at a price which the people can afford to pay. In Great Britain the average price of liquid milk is much higher than in any other country of North-West Europe or in the United States. In Sweden, with milk at 1½d. a pint, the annual consumption of the non-agricultural population is 420 pints per head; in Great Britain, where the average price is more than twice as high, it was only 150 pints in *1934–5*. In the Council's opinion no general reduction of price which seems commercially feasible in the near future will of itself be enough to bring milk within the range of mothers and children in less well-to-do homes. Milk must therefore be made available for these people as a matter of social policy.

The proposal of the Council is that milk should be purchasable at 1½d. a pint for all expectant and nursing mothers and children under school age in families of insured workers and others of like economic status, and that the quantity available at that price should be up to two pints a day for mothers and one pint for children. Its view is that a substantial increase in consumption of milk by these people is of such vital importance to public health that it would be in the national interest to subsidize existing retail prices (averaging 2s. 2d. a gallon) sufficiently to bring milk within reach of the poorest. But the position of the milk industry makes such a costly resort unnecessary. Rather more than one-third of the milk sold through the Milk Marketing Board is sold for manufacture at prices which average at less than 5½d. a gallon. Part of this flood of cheap milk should be diverted to the needs of mothers and children. The Council calculates that a sufficient supply of milk could be made available, if producers and distributors agreed on some concession, at 1s. 5d. a gallon. The gap between this figure and the 1s. a gallon to be charged for the milk would need to be bridged by a subsidy from the Exchequer. The scheme should be organized through the public health authorities and the milk distributed to the homes of the consumers. It is estimated that in Great Britain there are about three and a half million expectant and nursing mothers and children under 5 of this economic status. If they became eligible for cheap milk and their demands averaged only half a pint a day the total consumption at the cheap prices would be just under eighty million gallons a year, entailing, at 5d. a gallon, a national subsidy of £1,663,000.

The principle of differential prices is of course not new; many industries—and professions too—charge lower prices to certain consumers or clients in order to meet demands at different levels. The milk producers themselves practise price discrimination when they charge 3½d. a gallon for milk which is to be made into butter and cheese, and 1s. 3d. when it is to be resold to the housewife. The producers enjoy a monopoly of the home market, have statutory power to fix the price of their produce,

[1] *British Medical Journal*, April 10, p. 771.

and receive substantial assistance from the Exchequer. To enable the Board to maintain present pool prices and at the same time to sell manufacturing milk at world prices, the public are not only paying a relatively high price as consumers, but as taxpayers they are subsidizing the sale of milk for manufacture. The good will of the public for the Marketing Board, on which its success to some extent depends, will be more readily accorded if it can be shown that the Board's monopoly powers do not result in depriving a large section of the public of the milk essential for their children. The Council is also urging that milk should be supplied free for expectant mothers and young children in families where the money available for food is insufficient for full health. At present under most local authorities, even after a stringent income test has been satisfied, the milk is only supplied free when clinical symptoms reveal the need for additional nourishment. In the Ministry of Health's circular accompanying the Advisory's Committee's report it was urged that the scale of income for milk assistance should be so framed as not to render it difficult for any mothers to take advantage of the authorities' arrangements. The Council suggests that a basis should be laid down by the Minister in the light of nutritional requirements, possibly following the estimate made by the Nutrition Committee of the British Medical Association as to the minimum costs of satisfying food requirements, revised to conform with the milk recommendations of the Advisory Committee, or the Advisory Committee itself might be asked to draw up a scale for the guidance of local authorities.

Some discussion on milk policy arose during a session of the Imperial Social Hygiene Congress held in London last week. Sir John Boyd Orr, in an address on nutrition, said that the primary policy of the Government should be to ensure that an amount of milk adequate for health is brought within the purchasing power of every member of the community. The representative of a county council asked whether it was wise to stress milk so far as adults were concerned, in view of the fact that this might blind people to the need for a good mixed diet. Sir John Orr replied that milk was not an essential food for anybody; even for young children a perfect diet could be devised without milk at all; but the reason for emphasizing milk was because the common diet of the poorer population, with its large reliance on white bread, sugar, and margarine, was deficient, and milk offered itself as the cheapest means of correcting nutritional faults. For those who could command a varied diet of tomatoes, green vegetables, and so forth milk was unnecessary.

GASTRIC DISORDER AMONG BUSMEN

In the *British Medical Journal* of July 10 (p. 69) there appeared a full summary of the contents of the report by Dr. A. Bradford Hill on the sickness experience of London transport workers, published by the Industrial Health Research Board.[1] The report is so clearly written that we need not again summarize the findings. It is sufficient to say that the scope of the medico-hygienic problem still requiring investigation has been satisfactorily defined, and that it should now be possible, given the frank co-operation of those having expert knowledge of the administrative, medical, and psychological questions involved, to reach a solution. We think, however, that both what was said before the report appeared and the way the report has been received give cause for reflection.

Since in the most populous European states free discussion of subjects which have, or are thought to have, political or social implications is about as dangerous as criticism of the Government under Tiberius, we are not unnaturally proud of the very different position in our own country. But not a little of what has appeared in the public press since the bus strike must make the judicious grieve. So far as this derives from party spirit, from a desire to make a party score on one side or the other, we have no concern with it. Even when it is suggested that the correct plan of a scientific investigation was settled long ago by the Queen of Hearts, "Sentence first—verdict afterwards," we can afford to smile. But there is more than a suspicion that these eccentricities are not wholly confined to politicians. In the first place we do not think that either in the evidence taken by or in the report of the tribunal appointed at the time of the strike, the public were sufficiently informed of the facts (*a*) that a scientific investigation had been proceeding for more than three years; (*b*) that, as in every investigation of the aetiology of sickness, an adequate "control" group must be obtained; (*c*) that the method of investigation must be statistical, but a statistical investigation checked at every point by medical and administrative experts.

There was a tendency to depreciate the statistical method as inferior to some other, not clearly defined, more scientific approach. The public are still ignorant of the amount of work done by the Medical Research Council and the Industrial Health Research Board—work in which members of the medical profession take a large part—in focusing knowledge of industrial health problems. In this particular case they and their investigators have been done considerably less than justice. No prob-

[1] Report No. 79. H.M. Stationery Office (6d., postage extra).

lem can be solved until it has been correctly stated. Finally there have been signs of an extension of a habit which used to characterize some high-browed periodicals. We are all familiar with the supercilious reviewer who remarks that if Mr. X. had been acquainted with the important papers by Y. and Z. he would not have written his book at all or would have written it quite differently. In this case there has been a tendency for experts in particular fields to overemphasize the value of specialist knowledge. What has not been realized is that the problems of industrial sickness are essentially matters for team work, and that violent or scornful emphasis on this or that method of approach tends to destroy the spirit of co-operation without which team work is impossible.

THE REPAIR OF ANAEMIA

In health the blood is maintained with surprising constancy at a level about 5,000,000 red cells and 100 per cent. of haemoglobin per c.mm. The length of life of the red cell is not known with any certainty, but it is supposed to be from twenty to fifty days. Assuming a span of life of twenty-five days, calculation shows that some 200,000 old red cells must die and 200,000 new red cells must enter the circulation every day. Anaemia may result from an increased rate of destruction or a decreased rate of production of red cells or from a diminution in their length of life. In pernicious anaemia the poverty of the blood and the megaloblastic degeneration of the bone-marrow are nowadays attributed to a decreased rate of production of red cells from lack of essential principles. There is a close correlation between the degree of anaemia, the extent of hyperplasia of the bone-marrow, and the height and duration of the reticulocyte crisis on the inception of treatment with optimum doses of liver or other effective substances.[1] Mathematical formulae have been devised whereby the expected reticulocyte crisis can be calculated, and such formulae are of value in testing therapeutic preparations. The anaemia which follows a sudden fall in the number of circulating red cells, as from a haemorrhage or a crisis of haemolysis, is repaired spontaneously within a few weeks, and we have been accustomed to attribute this repair to an increase in the rate of erythropoiesis. Such an increase could be explained either by a more rapid maturation of the cells through the stages of erythroblast and reticulocyte to mature erythrocyte, which seems *a priori* improbable, or to an increase in the amount of haemopoietic tissue, which is in fact confirmed by pathological findings. This explanation is challenged by Schiodt,[2] who has made careful observations on blood regeneration in man after haematemesis and melaena. He finds that there is a distinct correlation between the minimal blood count and the daily rise in red blood cells. The more the patient has bled the faster the blood mounts, and all the curves, though starting at different levels, tend to meet at the level of 4.54 million red cells per c.mm. about forty days after the haemorrhage. This phenomenon, and especially the straight line character of the curves, could quite simply be explained by assuming that the rate of blood formation and the longevity of the red cells remain constant. The number of red cells removed from the circulation by death, however, is directly proportional to the total count. If the red cell count falls to 2.5 million only 100,000 red cells will die every day, and there is therefore a natural surplus of 100,000 to correct the anaemia. The theory is perhaps too ingenious, and it does not explain the reticulocyte crisis and the hyperplasia of the bone-marrow which accompany a haemorrhagic or a haemolytic anaemia. But if the rate of production of red cells is actually accelerated for a time it is surprising that repair does not more often overshoot the mark and produce an erythrocytosis. Moreover, one would have expected a sigmoid curve rather than the straight line that Schiodt found. Schiodt's patients were treated by Meulengracht with early feeding. Iron and blood transfusion had no obvious effect on the rate of repair of the anaemia, but it was retarded by fasting or a strict ulcer cure. It is also possible that the use of alkalis may have acted as a check to the attainment of the normal level of 5,000,000 red cells during the period of observation.

VISIT OF BRITISH SURGEONS TO PARIS

A party of thirty surgeons representing the Royal College of Surgeons of England and the Association of Surgeons visited Paris on Monday and Tuesday, July 5 and 6, at the invitation of the Académie de Chirurgie. They were received by the president, Dr. Baumgartner, the secretary, Dr. Louis Bazy, and other members of the Académie. On Monday morning they visited the anti-cancer centre at Villejuif, where they were received by the director, M. Roussy, by M. Bertillon, Mme Simone Labord, and the heads of the various departments. The anti-cancer organization of France, distributed over twenty centres, was explained by Professor Roussy, who then showed the party the extensive and important clinic and laboratories of Villejuif. Of perhaps special interest were the radium unit, designed by Mme Simone Labord, and containing five grammes of radium, and the magnificent x-ray plant, of which one unit could reach an intensity of 600,000 volts. Leaving Villejuif the party was entertained at lunch at the Hôtel Foyot, one of the oldest and most famous restaurants of Paris, and afterwards met in conference with the Académie de Chirurgie at its house in the Rue de Seine. After an opening address the president announced that the French Government had conferred upon Sir Cuthbert Wallace, Professor George Gask, and Mr. H. S. Souttar the high honour of the Croix d'Officier de la Legion d'Honneur in recognition of the part they had played in establishing relations and friendship between the Royal College of Surgeons of England and the Académie de Chirurgie. By the authority of the President of the Republic Dr. Baumgartner

decorated each of the recipients in due form. Sir Cuthbert Wallace responded in suitable terms, expressing the deep appreciation which all those present felt of the honour which had been conferred by the President of the French Republic upon the Royal College of Surgeons of England. Several important papers were presented by members of the Académie on the subject of surgical infarctions, and the members then adjourned to the physiological laboratory, where Professor Binet had prepared a series of experiments demonstrating points which had been made in the discussion. In the evening the party, and the ladies who accompanied them, were entertained at dinner by the Académie de Chirurgie at the Hotel Ritz. The occasion was a very brilliant one, and the presidents of the Académie de Chirurgie and the Royal College of Surgeons expressed in short but admirable terms the friendly relations of the two great societies. Tuesday morning was devoted to visits to the hospitals of Paris, where a series of operations had been arranged, and the meeting closed with a visit to the Château of Chantilly, which was specially thrown open for the party by the French Government. The meeting was felt by all to be a great success, and to mark another step in what is hoped may be a long and close friendship between the surgeons of France and of Great Britain.

FURTHER WORK ON THE HYPOTHALAMUS

Localization of function in the brain has been made possible by two distinct methods of approach. One is to expose the area to be investigated and observe the effects of stimulation by accurately placed electrodes. The other is either to remove or to damage the area and to study the disorder produced by loss of function of that particular part of the brain. A localized disease process may either confirm the results of such experiments or, in inoperable areas of the brain, serve as a substitute for them. Both these methods have been used in recent research on that mysterious region of the brain, the hypothalamus. For some time it has been known that electrical stimulation of the anterior part of the hypothalamus gives rise to sweating of the footpads in animals, and there has also been convincing evidence that the hypothalmus contributes to the maintenance of body temperature. Masserman[1] has carried out a series of experiments on animals which go to show that sodium amytal—and possibly barbiturate drugs of a similar nature—has a specific inhibitory effect on the sympathetic reactions of the hypothalamus. A study of the influence of a disease process affecting the hypothalamus on the heat regulation of the body has been made by Finkelman and Stephens,[2] who measured the increase in oxygen consumption and the ability to maintain the normal temperature on exposure to cold in patients with chronic epidemic encephalitis as compared with normal subjects. They found that heat regulation was defective in chronic encephalitis, there being a greater loss in temperature and a smaller gain in oxygen consumption than in normal controls. The greatest loss in temperature on exposure to cold was found in patients with encephalitis who had been treated with atropine. The authors deduce from the findings here briefly outlined that atropine disturbs the heat-regulating centre in the hypothalamus, and they ascribe the disorder of heat regulation in epidemic encephalitis to a lesion at this site. In a disease in which the lesions are so widespread further work is needed to confirm these views.

ANAESTHESIA IN GENERAL PRACTICE

There appears in this week's issue of the *Journal* the first of a short series of signed articles on anaesthesia in general practice. Anaesthesia has not lagged behind other branches of medicine, and during the past few years has made rapid advances. The comfort of the patient, the importance of allaying anxiety, the choice of anaesthetic agents for different types of patient and for different types of operation are all matters which have received, and are receiving, the attention of those who specialize in the subject, aided as they are by the researches of the chemist and the physiologist. Although anaesthesia is now incomparably safer than it was years ago, new agents introduce new risks, and new methods of dealing with these have to be devised. These and other questions will be considered in the series, which is intended first and foremost for men in general practice, especially for those not within easy reach of elaborate equipment or expert assistance. It therefore seemed apposite to start with a paper by someone actually in general practice, so that the articles that follow may be read against the background of experience of practical difficulties and needs—a background provided by the article at page 126 by Dr. Helen Lukis, who was awarded the Sir Charles Hastings prize in 1934 for her clinical study entitled "The Problems of Anaesthesia in General Practice."

BONOMO AND THE ITCH-MITE

Two hundred and fifty years ago a young doctor of Leghorn identified the itch-mite and refuted the belief that scabies was a disease of internal origin. The revival of interest in Bonomo is due to Dr. Ugo Faucci, whose researches have shown how this discovery furthered the understanding of contagion. When the Italian Society of Dermatology met last month at Leghorn in honour of Bonomo and his collaborator Cestoni, Dr. Faucci brought to light the correspondence of Bonomo with Lancisi, the famous papal physician.[1] The letters are amusing and instructive. Bonomo had submitted his book to the Congresso medico Romano, a private medical society, and Lancisi tells him of its reception. He warns him not to believe everything that he thinks he has seen through his microscope, and says that he is too bold in generalizing about the parasitic origin and

[1] Ugo Faucci: *La Polemica Bonomo-Lancisi sull' origine acarica della scabbia.* Livorno. 1937.

contagious nature of scabies because he has found "worms" in certain cases. When Bonomo repeats his claims Lancisi answers with a formidable display of learning. The English reader will notice that he quotes Willis among many authorities, ancient and modern, including the Bible, to show that scabies can arise spontaneously. Bonomo sent him in return some doggerel verses on the spontaneous generation of insects, and this time Lancisi answers more sternly, hinting that Bonomo's ideas are very near heresy. In a final note the young man admits that his master cannot be mistaken, and that scabies may sometimes arise without contagion. Dr. Faucci suggests that Bonomo's submission was more politic than sincere. He has annotated the letters from a wide knowledge of the period, and they give us an intimate view of medical life in Italy at the close of the seventeenth century.

CANNED FOOD

The canned food of to-day is hermetically sealed and processed in a metal container. The original containers in this method of preserving, as first used by Nicholas Appert in Paris in 1809, were glass bottles. Soon afterwards Durand in England began to employ tin canisters, which were a notable improvement, since they were less fragile than the bottles and also more amenable to heating and sealing. From these beginnings the industry grew, slowly at first, more rapidly later. Great Britain now heads the list of importers. In 1919, as a result of war shortages, there was a sudden increase in the volume of canned imports conveyed to this country. Just as Appert's bottled food was devised for armies in the field, so in these latter days its canned counterpart has already contributed to the "iron ration" of Britain, and may again. Economically the canning industry holds an assured place. Scientifically it has outgrown its early empirical stages and is developing along the lines of an exactly controlled system. A survey of the various procedures now favoured by packing houses is well presented in a recent work by O. and T. W. Jones.[1] The aim of the authors has been to put together a book of practical value. The general principles are broadly laid down and, where necessary, amplified in detail according to the special conditions of the process under consideration. Beginning with the selection and preliminary preparation of the food, the authors next discuss the various forms of the can, indicate the most suitable grades of tin-plate, and explain the purpose of processing. They detail the management of the cannery laboratory. They devote attention to water supply and the question of the hardness of water, including its softening where required. Other topics which are set forth in the same informative manner include general chemical analysis, the microbiology of canning, the preparation of culture media, the food-spoiling organisms, and the effects of canning on nutritive values. A pamphlet by H. B. Cronshaw[2] is concerned more particularly with the wholesomeness of canned foods. Both the principles and procedure of canning are set forth in a concise and lucid manner. Metallic contamination, gas production, and bacterial growth are discussed. Ptomaine poisoning is rightly discounted and medical testimony to the safety of canned foods is aptly quoted. The pamphlet ends with the words: "After a century and a quarter of practical experience the public confidence in canned foods to-day is greater than ever before." This confidence is, we think, in general not misplaced.

EGYPT AND THE DRUG TRAFFIC

In his annual report to the Egyptian Narcotics Bureau for 1936, T. W. Russell Pasha chronicles his continuous warfare against illicit traffickers in dangerous drugs. Two new branches of the Central Bureau have been opened at Tanta and Ayût; the destruction of flowering poppy-crops has been energetically pursued, and the arrest of persons trafficking in hashish and heroin vigorously proceeded with. The danger spot for international traffic in narcotics is Suez, where the door is wide open for smugglers. It is, according to Russell, through the Suez Canal that the bulk of heroin from Manchukuo finds its way to America. The report states "the fact is now beyond dispute that the world source of illicit white drugs is China north of the Wall and for some distance south of it." These areas are nominally under Japanese jurisdiction, but it appears that the trade in opium and heroin is an open business concern and is not considered to be illegal. It is alleged that ships' personnel and passengers can buy a kilo of heroin in Tientsin for 5,000 francs and sell it at Port Said and Suez to purchasers for 12,000 francs; these again dispose of it at great profit to themselves. The urgent need for better port control is stressed. Bumboatmen, cargo workers, etc., who await the arrival of ships, are potential smugglers. As there are some 400 or 500 vessels arriving every month, many of which are from suspect ports in China, India, and the Persian Gulf (three-fourths of which carry oriental crews), the peril of world-wide distribution of narcotics from this centre is evident. These facts, Russell urges, must be boldly stated at Geneva, and the co-operation of Great Britain, the United States, and other countries concerned sought for and secured if any real advance is to be made in the suppression of illicit traffic.

THE HALF-YEARLY INDEXES

The usual half-yearly indexes to the *Journal* and to the *Supplement* and *Epitome* have been prepared and will be ready shortly; they will, however, not be issued with all copies of the *Journal*, but only to those readers who ask for them. Any member or subscriber who wishes to have one or all of the indexes can obtain what he wants, post free, by sending a postcard notifying his desire to the Finance Department, British Medical Association House, Tavistock Square, W.C.1. Those wishing to receive the indexes regularly as published should intimate this.

ANAESTHESIA IN GENERAL PRACTICE

This is one of a series of articles, contributed by invitation

CHOICE OF ANAESTHETIC IN GENERAL PRACTICE

BY

HELEN LUKIS, M.D.

The choice of anaesthetic in general practice does not, of course, differ in essentials from the similar problem in hospital, and the main guides must be the nature of the operation, the idiosyncrasies of the patient, and the skill and individual preferences of the administrator. There are, however, certain difficulties, specific to general practice, which make some of the newer methods impracticable for the family doctor. The general nature of his work, which makes him a man who is expected to know something about everything, makes it impossible for him to know everything about any subject, and the mastery of a special technique may require more study, time, and experience than he is able to spare. He may not give an anaesthetic for several weeks on end, and then be called upon to give a series; at least 60 per cent. of his cases will consist of dental gases and minor operations, while 50 per cent. of the remainder will be emergency cases in which there are so many other details to arrange (it is not unusual for the doubtful acute abdomen and the surgeon to arrive at the nursing home together) that there is very little time for complications of anaesthetic technique.

Time is an all-important factor, because a day is not, unfortunately, infinitely elastic, and the one or two hours required for an operation can perhaps only be done by leaving undone something which ought to have been done; any technique, therefore, which necessitates prolonged preparation, visiting at a specified time beforehand, or an extension of operative time must be considered not only in relation to the patient but with regard to the needs of other sick people.

The general practitioner's close personal relationship to his patient makes it essential that he shall not use methods too experimental, too dangerous, or too unusual, while the peripatetic nature of his work makes portability a consideration. He lacks adequate storage space, so that bulk is undesirable, and his chronic lack of skilled assistance makes it important that the apparatus should not require elaborate upkeep; rust, the perishability of rubber, the insidious passage of time, and the limited space at his disposal make it necessary to exercise a rigorous economy over the apparatus he has to maintain. His ideal anaesthetic, therefore, should be 100 per cent. safe; easily portable; not so complicated that it takes time to assemble or requires prolonged pre-operative attention; not liable to be found out of order after three or four months' disuse; neither taking up too much room, nor requiring stores of spare parts, nor liable to run out in the middle of an operation; not too expensive, and as pleasant as possible to the patient. Bearing these considerations in mind, the actual choice of anaesthetic may be discussed under the headings: (1) local anaesthesia; and (2) general anaesthesia—non-inhalational and inhalational.

Local Anaesthesia

Local anaesthesia would appear to offer many advantages: the difficulty of obtaining a second doctor on, say, a fine Sunday makes any method which would enable one to operate single-handed in an emergency worthy of consideration.

Superficial local anaesthesia is achieved by spraying or plugging with the chosen solution, or by freezing. The former method is applied chiefly to the mucous membranes: it is the anaesthetic of choice in most ophthalmic operations, except glaucoma and excision, and in most nasal operations. It is possible in a fairly stoical adult to perform a myringotomy under 20 per cent. cocaine and adrenaline, while the application of novocain to a cut surface makes suturing almost painless if a fine needle is used. Anaesthesia from freezing is of so short a duration that it is only available for a limited number of operations, such as the incision of superficial abscesses.

Injections of novocain or allied substances have the advantages that the anaesthesia is of a longer duration than gas or ethyl chloride in minor operations, no second doctor is required, there are none of the pre- or post-operative problems connected with the unconscious patient, there is greater safety, and the addition of adrenaline makes the field of operation relatively bloodless. On the other hand there are certain disadvantages. Neurotic, frightened, or hysterical patients, and young children do not react well to the thought of consciousness during an operation; a considerable number of people show more or less serious idiosyncrasies; sepsis, which constitutes the greater part of the minor surgery of general practice, is a definite contraindication; and the range of anaesthesia is rather limited unless the drugs are used in great bulk (which presents problems of sterilization and skilled assistance) and by regional infiltration of the nerves supplying the part, which demands specialized anatomical knowledge which, to quote the national health insurance regulations, "general practitioners as a class cannot be expected to possess." The principal value of regional anaesthesia is in affections of the terminal phalanges (paronychia, whitlow, foreign body, etc.); the digital nerves can easily be blocked by 2 per cent. novocain injected at either side of the first phalanx at the level of the web between the fingers.

Böhler's method of reducing fractures by the injection of 20 to 40 c.cm. of 2 per cent. novocain into the haematoma is very tempting, but the difficulties of exact localization of the fracture and of sterilizing and keeping sterile such a large quantity of solution without a trained and skilled assistant are very great.

Spinal anaesthesia presents enormous difficulties to the occasional anaesthetist, who has so few opportunities of practising its technique, and should, in my opinion, be left entirely to the specialist.

Non-inhalational General Anaesthesia

Non-inhalational general anaesthesia may be administered rectally or intravenously. Rectal administration is, without question, one of the pleasantest ways of inducing narcosis; the drug can be given as a simple enema to an unknowing patient, who falls asleep and wakes up many hours later without any consciousness of having been operated upon. The method cannot be used in diseases of the rectum or anus, and may set up an acute colitis.

Avertin, the drug most commonly used, appears to come in safety between chloroform and ether. In doses guaranteed to produce surgical anaesthesia it is more dangerous, and it frequently, therefore, requires additional inhalation anaesthesia. The apparatus is bulky, breakable, and awkward to pack; it requires elaborate and somewhat complicated calculations of dosage, takes up a full hour of pre-operative time, and the patient requires four to twenty-four hours of close post-operative attention. It must be heated to 37° C. and not over 40° C., cannot be prepared more than an hour before the operation, nor, under general practice conditions, can its administration be left to an assistant: in short, it is an invaluable weapon in the hands of a specialist and a very dangerous one in those of the family doctor.

Intravenous anaesthesia is dramatically quick in onset; there is no mask or feeling of suffocation, and post-operative gastric and pulmonary complications are rare. Veins are hard to find in children, the fat, and shocked or exsanguinated cases, and the duration of both surgical anaesthesia and post-operative coma are very variable. Nembutal has been extensively used, but hardly seems safe enough for the family doctor. One drug, however—evipan sodium—is to the general practitioner what avertin is to the specialist. Used in the doses recommended for minor operations, when 10 c.cm. is rarely exceeded, this drug is almost 100 per cent. safe; its efficiency is only limited by the difficulties of intravenous medication; it is very pleasant to take, keeps well, and requires very little pre-operative time. The apparatus required is:

10 c.cm. syringe, kept sterile in ether.

Two intravenous needles, kept sterile in ether.

Package of evipan containing ampoules of the drug and distilled water.

A file.

A rubber catheter or tourniquet.

A small dressing, two swabs, a bandage.

A mouth prop or gag.

The ether can be used to sterilize the skin, and the needles will not rust as they do if kept in spirit.

The freshly made solution of the drug is injected slowly into the vein while the patient counts: when he stops the amount given is noted, and as much again is inserted.

Evipan produces an ideal anaesthesia for many of the minor operations of general practice, such as dental extractions, fractures, acute septic infections, etc., because the patient has one to two hours' post-operative sleep, which is very valuable in these painful conditions. There is often, however, a period of semi-intoxication, which makes the drug entirely unsuited for use in the consulting room or dentist's surgery.

Inhalational Anaesthesia

It will appear from the foregoing remarks that some kind of inhalational anaesthesia will be the general practitioner's choice in most cases, and the decision will rest between gas and ethyl chloride for short operations, and between gas and oxygen, chloroform, and ether for the more prolonged ones.

The advantages and disadvantages of nitrous oxide are too well known to need any discussion, but many do not realize the value of ethyl chloride for the minor operations of general practice. It is easily portable, gives an anaesthesia lasting about twice as long as that from a single dose of nitrous oxide, is so rapid in action that difficult patients such as struggling children are anaesthetized in a couple of breaths, and recovery is sufficiently rapid to make it suitable for consulting-room use. The most diverse opinions are held about its safety, but American authorities put the mortality at about 1 in 13,365 cases. It may be given on an open mask, when the dosage is difficult to control, but I prefer to give from 3 to 5 c.cm. in a closed bag. The face-piece is slowly approximated to the face while the child counts or talks, and anaesthesia usually supervenes without any struggling or distress. When the breathing becomes stertorous the face-piece is removed and the operation performed. Ethyl chloride is not suitable for continuous administration, and nearly all the fatalities have followed attempts to prolong the anaesthesia by giving supplementary doses.

Gas and oxygen is, of course, the ideal anaesthetic from one point of view, because it is the nearest approach to 100 per cent. safety we possess. It has unfortunately, however, great drawbacks. The apparatus is costly and bulky, liable to mechanical breakdowns, and requires constant and careful maintenance to keep it in working order. While many of us are fortunate enough to have the use of an apparatus at our cottage hospital, we are reduced to chloroform or ether for the majority of our cases outside.

If only chloroform were safe it would be the ideal anaesthetic for general practice. It is the most easily portable and least bulky of all the available drugs; it never fails to anaesthetize, is far more pleasant than ether, is non-inflammable, and gives a delightful, quiet, and uncongested sleep. Operations such as tonsillectomy and large-scale dental extractions, for example, which may be a shambles under ether, are a delight under chloroform. Nevertheless, the fact remains that figures collected by hundreds of different observers under all sorts of different conditions show that there is a steady mortality of 1 in 3,000 with this drug, and that this mortality tends to be of that most heartbreaking type—that is, the unexpected case—the apparently healthy young adult who snuffs out under some comparatively trivial operation such as circumcision or tonsillectomy.

Ether is probably rather more than twice as safe as chloroform. In addition, its victims are much more likely to be people who are bad anaesthetic risks, and whose death does not come as such a shocking tragedy, and for this reason it must remain the anaesthetic of choice for most cases. It has, however, one great and real drawback, which is its inflammability, and there will always be cases in which it cannot be used for this reason. In 208 recent confinements, for instance, there were only seven in which there was not a naked flame in the room. In forty-seven there were gas or electric fires, which could be turned out easily, and in 154 coal fires, at distances from the patient ranging from three to twelve feet. The lighting was by gas in twenty-seven instances, lamps in eleven, and candles, waved wildly by the midwife, in five. Under such conditions of lighting and heating it is a lucky general practitioner who will not have to have recourse at some times to the dangerous but very satisfying anaesthesia of chloroform.

My choice for the major operations of general practice is to induce with 5 drachms exactly of C_2E_2. A gamgee square with a large hole in the centre (a torn hole is much better than a cut one) is placed on the patient's face "to keep anything out of the eyes." The mask is held about three inches away, and the C_2E_2 is poured on drop by drop while the patient counts or talks. The mask is slowly approximated to the patient's face until it rests on the gamgee shortly before the 5 drachms of

mixture are exhausted. If the change to ether is then made slowly a smooth induction without coughing or struggling is nearly always achieved.

To sum up, then, the choice of anaesthetic in general practice will be along these lines.

Minor Operations.—Nitrous oxide, ethyl chloride, or local anaesthesia for surgery use. Evipan sodium for a patient in bed.

Major Operations.—Gas and oxygen in hospital, C_2E_3—ether sequence in general. Chloroform if close to naked flame.

NEW BLOCK AT ST. BARTHOLOMEW'S

OPENING BY QUEEN MARY

Queen Mary visited St. Bartholomew's Hospital on July 8 to open the new medical block, which is to be known as the "King George V Building," an erection of six floors, occupying the site of the old south block, with accommodation for 253 beds. The ceremony took place in a large marquee erected on one side of the hospital square adjoining the new building. Her Majesty was received on arrival by Lord Stanmore, treasurer of the hospital, the Earl of Strafford, senior almoner, and the Countess of Strafford, president of the hospital women's guild. Among those presented were Dr. Alexander Gow, senior physician, Mr. Harold Wilson, senior surgeon, Dr. George Graham, physician, Mr. W. Girling Ball, surgeon and dean of the medical college, and Miss Helen Dey, matron and superintendent of nursing.

After prayers by the Archdeacon of London, Lord Stanmore read an address recalling the history of the hospital, how for eight hundred years on that site, as its founder Rahere ordained, it had admitted the sick, the wounded, and women labouring with child. Just four hundred years ago, as a result of the Reformation, with the dissolution of the monastery whose canons, with sisters, had ministered to the spiritual and physical needs of the patients, the hospital was left almost derelict, whereupon the Mayor of London, Sir Richard Gresham, and the Aldermen and Commonalty presented a petition to Henry VIII, who in consequence refounded the institution and enabled the work of tending the sick poor to be resumed. During these last four hundred years the patients had been treated by physicians, surgeons, and nurses, whose work had added to the prestige of the hospital. Lord Stanmore recalled previous visits of Queen Mary. She had accompanied King George V in 1907 on the occasion of the opening of the out-patients' department, and in 1921 had laid the foundation stone of the nurses' home, which bore her name. (He might have added that she also came to the hospital in 1917 and distributed parcels to a number of patients who had been injured in an air raid in the locality.) He concluded by saying that the opening of this block of medical wards with the most modern equipment would enable the ancient hospital to retain the position it had always held in the forefront of the healing art and allow a larger number of patients to be treated in accordance with the highest ideals of modern medicine. The Queen then declared the new building open, and after the architect, Mr. T. A. Lodge, had been presented she proceeded to inspect the block, also visiting the British Red Cross library and the nurses' home

The New Medical Block

Each of five floors of the building (except the ground floor, which has slightly less accommodation) is divided into two units of twenty-five beds, each unit comprising a large ward of twenty-three beds and two single-bed wards. Attached to each unit also are sanitary rooms, ward kitchen, sisters' room, and linen room, and on each floor examination rooms, staff rooms, and rooms for various routine purposes. Each large ward is equipped with a sun balcony for beds facing south, and on the top of the building a solarium has been placed. The top floor contains an isolation unit of seven beds, also laboratories forming an extension of the Dunn laboratories built with the surgical block in 1930. There is also a lower ground floor with rest and common rooms for patients' friends, departments for cardiographic work, and a number of stores and offices. The equipment throughout is of the most modern type; particular attention has been given to the fittings, and as far as possible all cupboards have been built in. The building is considerably larger than the block it replaces, and careful planning has been necessary to secure maximum light and ventilation to the various rooms. The eighteenth century appearance of the hospital square, of which Bart's is legitimately proud, has been preserved by the use of Portland stone facings to the part of the building which adjoins the square, and as far as possible the old stone, used when the old building was constructed two hundred years ago, has been re-used for the purpose.

TRAVELLING FELLOWSHIPS IN TUBERCULOSIS

The Medical Research Council has awarded Dorothy Temple Cross Research Fellowships to the following candidates intending to study problems of tuberculosis at centres abroad during the academic year 1937–8:—

BRIAN CONNOR THOMPSON, M.D., Cantab., formerly Assistant Tuberculosis Officer, Durham County Council (renewal of present fellowship for three months).

RONALD HERBERT ROBERT BELSEY, M.B. Lond., F.R.C.S., Resident Surgical Officer, Hospital for Consumption and Diseases of the Chest, Brompton, London.

BRIAN MAURICE MAXWELL, M.D. Belf., Senior Assistant Medical Officer, Cheshire Joint Sanatorium, Market Drayton.

OSWALD SYDNEY TUBBS, B.Ch.Cantab., F.R.C.S., Chief Assistant to a Surgical Unit, St. Bartholomew's Hospital, London.

ENID MARY WILLIAMS, B.Sc., M.D., Wales, Assistant Lecturer in Tuberculosis, Welsh National School of Medicine, Cardiff.

The next annual meeting of the International Society of Medical Hydrology, which is open to non-members on payment of a fee of £1, will be held in Germany, at Frankfurt and the neighbouring spas, from October 17 to 22. The members of the Congress will be housed in Wiesbaden throughout, but the ceremonial opening meeting and first discussion will be held at Frankfurt. The other spas to be visited are Bad Nauheim and Bad Ems, at each of which meetings will be held, and a flying visit has been arranged to Schwalbach and Schlangenbad, on the way to Eltville, where a Rhineland vintage festival will take place. After the meeting there will be optional excursions to Kissingen, Heidelberg, Würzburg, Worms, Baden-Baden, and other places. The inclusive charge for accommodation and excursions during the meeting is RM. 85 (about £7); the party to travel from London on October 16. The subjects for discussion are (1) bioclimatology; (2) psychological factors of health resort practice (one of the openers being Dr. R. G. Gordon of Bath); and (3) natural history of peloids (moors and muds). There will also be demonstrations of laboratory and experimental work. All information may be had from the I.S.M.H., 109, Kingsway, London, W.C.2.

NEW TRAINING COLLEGE FOR CRIPPLES

THE STANMORE ENTERPRISE

A college for the training of crippled lads in useful trades has been established in association with the Royal National Orthopaedic Hospital in the ample grounds of the country branch of that institution at Stanmore. The college is to be formally opened during the present month (July) on the completion of the building, but in fact it has been functioning, though not to its full capacity, for the greater part of a year.

In this woodland country of Middlesex a very pleasing group of buildings has been put up, the lay-out of which is difficult to convey in a photograph, where one hundred male cripples between the ages of 16 and 22 will be given a chance, despite their physical disabilities, of going out into the world as self-supporting individuals. The single-story buildings, including the dormitories, have been arranged in the form of a wide arc so as to secure the maximum sunshine and air. In spite of the fact that the building is on sloping ground, there is not one step which the cripple has to mind.

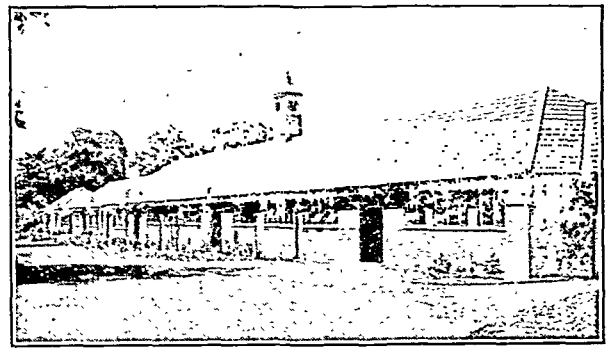

FIG. 1.—The Cripples' Training College, Stanmore.

Although it is controlled by the hospital committee and enjoys some of the hospital services, the college is quite separate from the hospital. But it must be considered a significant extension of the hospital idea that the care for the disabled should include not only their physical compensation as far as that may be possible, but the provision of training for a craft which will enable them on final discharge to meet life more or less on equal terms. The college is a new undertaking so far as the Royal National Orthopaedic Hospital is concerned, but it really continues the work of the Home for Crippled Boys, Woolsthorpe House, Wright's Lane, Kensington, which was founded in 1865 to board and lodge cripples and teach them a trade. The hospital took over this institution, with the boys actually in training, and these boys, numbering forty-eight, have formed the nucleus of the Stanmore college, which now that it is completed will accommodate 100. The cost of the new buildings has amounted to nearly £70,000.

FIG. 2.—At work in the boot-making shop.

The Course of Training

The college is approved by the Board of Education, which has authorized local authorities to pay £90 per annum for each trainee, with entitlement to the 50 per cent. grant made by the Board. The boys are generally sent to the college by local authorities or social or philanthropic organizations. In very exceptional cases they may be admitted slightly below the age of 16, but that is not favoured. The course of training covers a minimum period of three years.

The trades taught, all under expert instruction, are boot-making (surgical and ordinary) with repairs; mattress-making and upholstery; painting and sign-writing; general woodwork and cabinet-making; tailoring; and watch and clock repairing. Other trades may be included as the organization develops. A whole-time schoolmaster is employed, and the lads in classes all have an hour's general education a day. The hours of work or instruction are from 9 to 5, with an hour's interval, and then the lads are free of restraint, except that they are expected to be in by a certain hour.

Accommodation and Resources

A tour of the college proved this to be one of the pleasantest places of the kind we have ever visited. Indeed, the only drawback is that the working and domestic conditions are so cheerful and healthy that when the students eventually go out into workshops less clean and spacious and orderly, and into lodgings lacking these refinements and amenities, they will be aware of an unpleasant change in their circumstances. Nowhere is there any institutional atmosphere. The dining hall, with the flowers on its tables, would do credit to a good-class hotel. There is a recreation room, with provision for table tennis, billiards, and other games, a quiet room where even the wireless is prohibited, and a concert hall of quite surprising size, equipped with stage and accessories. The dormitories, one of them constructed with specially large open windows for lads with a tuberculous tendency, have been arranged on the most modern hygienic principles, and there is also a self-contained sick bay with six beds for cases of temporary illness; any cases of serious illness are of course sent away to hospital. There is also ample bathing provision, and some of the baths have been so designed as to facilitate lads with certain deformities getting in and out. Outdoor sports are encouraged, and the football team is by all accounts quite formidable to its opponents. A scouts troop is well supported, and amateur dramatic and debating societies have discovered much hidden talent. The first copy of the stencilled college magazine, entitled *The Trainee*, entirely produced by the pupils themselves, is a remarkable production. As for the workshops themselves, these seemed to be, from the point of view of light and hygiene and convenience, model establishments under the Factories Acts. Although the disability in the case of some of those at work was obvious, many others were working in such positions that apart from close inspection they would have been taken as physically normal.

Organization

As already stated, the fee paid on behalf of each trainee is about £90 per annum, exclusive of certain extras which have to be paid by the responsible authority, such as the payment of the trainee's fare home for two periods of holiday in the year, also the provision and repair of any surgical boots or appliances, dental plates, and spectacles, as may be found necessary, and an outfit of clothing sufficient for use for twelve months after admission. The boys on entry are examined by the college medical officer as to their suitability for training, and a probation period of three months has to be completed to the satisfaction of the general managers. The college does not guarantee to get the lads jobs when they leave, but of course every effort is made to do so, and a careful register of the after-history is kept. Out of eleven recent departures nine of the boys taken over from the Wright's Lane home had already got jobs.

In the organization and opening of the workshops the college authorities have had the advantage of the help of Mr. J. Rhaiadr Jones, of the Derwen Cripples Training College, Oswestry, founded by Dame Agnes Hunt ten years ago for cripples of both sexes, and Mr. Jones is the honorary consulting superintendent of the Stanmore college, so that the Shropshire experience is available for the Middlesex venture. Dr. C. W. Durward, assistant resident medical superintendent of the country branch of the Royal National Orthopaedic Hospital, is the medical officer of the college, and Miss Williams, matron of the hospital, its lady superintendent. The college is also fortunate in its general manager, Capt. E. K. Wood, lately of the Indian Army, whose vigour and enterprise are evidently felt in every part of the undertaking.

BEIT MEMORIAL TRUST FOR MEDICAL RESEARCH

A meeting of the trustees of the Beit Memorial Fellowships for Medical Research was held on July 9 for the election of Fellows and other business. Deep regret was expressed at the death of Sir Edwin Deller, who since 1929 had given important help in his *ex officio* trusteeship as Principal of the University of London. He is succeeded in this *ex officio* appointment by the new Principal, Mr. Herbert L. Eason. The trustees noted with pleasure the distinctions received by two members of the Advisory Board during the past year: Professor J. C. G. Ledingham's knighthood, and the award to Sir Henry Dale of a Nobel prize for medicine. The honours gained by past Fellows include the K.C.B. granted to the present secretary of the Medical Research Council, Edward Mellanby, and J. McMichael's election to the Johnston and Lawrence Research Fellowship of the Royal Society.

Election of New Fellows

The total number of Fellowships held by full-time workers during the year 1936–7 remained unchanged at twenty-four.

The following elections were made:

Fourth Year Fellowships (value £500 per annum).—Robert Percival Cook, B.Sc., Ph.D. To continue his research on cholesterol metabolism in reference to the cause of atheroma in blood vessels (Institute of Biochemistry, University of Cambridge). Stuart Lawson Cowan, B.Sc. To continue his research on the neuro-muscular transmission of nervous excitation (Department of Pharmacology, University College, London). David Ezra Green, M.Sc., Ph.D. To continue his studies on intracellular enzymes and on the influence of vitamin B on oxidation processes (Institute of Biochemistry, University of Cambridge). Maurice Jowett, D.Sc., Ph.D. To continue his study of the action of narcotic drugs on the metabolism of the central nervous system (Biochemical Laboratory, Cardiff City Mental Hos. ital).

Junior Fellowships (normal value £400 per annum).—Ian Alfred Anderson, B.Sc., M.B., B.S. Proposed research: iron analyses of diets of women of the poorer classes at Aberdeen, and studies on the treatment of anaemia (Metabolic Research Laboratory, Aberdeen Royal Infirmary). Desmond Beall, B.A., Ph.D. Proposed research: sterol metabolism, with special reference to sex hormones (Department of Pathology, British Postgraduate Medical School, Hammersmith). James Gowans Chalmers, B.Sc. Proposed research: the role of polycyclic hydrocarbons in experimental tumour production (Glasgow Royal Cancer Hospital). Frederick Colin Courtice, B.Sc., D.Phil. Proposed research: the influence of insulin and endocrine secretions on the metabolism of prolonged muscular exercise (Physiology Laboratory, University of Oxford). Hugh Davson, B.Sc. Proposed research: the cause of primary chronic glaucoma of the eye (Department of Physiology and Biochemistry, University College, London). Thaddeus Rudolph Robert Mann, M.D., Ph.D. Proposed research: on intracellular compounds of blood pigment and the metabolism of oxalic acid in mammalian tissues (Molteno Institute, University of Cambridge). Antoinette Pirie, Ph.D. Proposed research: the metabolism of filterable organisms by analysis of their enzyme systems (Institute of Biochemistry, University of Cambridge). Derek Richter, B.Sc., D.Phil. Proposed reseach: the action of adrenaline and related substances on the metabolism of individual organs (Institute of Biochemistry, University of Cambridge).

All correspondence of Fellows and candidates should be addressed to Professor T. R. Elliott, M.D., F.R.S., honorary secretary, Beit Memorial Fellowships, University College Hospital Medical School, University Street, W.C.1.

Reports of Societies

OVARIAN EXTROVERSION

At a meeting of the North of England Obstetrical and Gynaecological Society held in Newcastle-upon-Tyne on June 11, with the president, Dr. J. W. BRIDE, in the chair, Dr. K. V. BAILEY read a further note on the operation of ovarian extroversion.

Dr. Bailey said that he had read his original communication on this subject to the North of England Obstetrical and Gynaecological Society in February, 1936. He had delayed setting down his conclusions until now because of two points raised at the time—namely, the advisability of carrying out a laparotomy which was not a surgical necessity, and the lack of proof of ovulation following operation even in the successful cases. He briefly outlined again the technique of his operation. A laparotomy was performed, and a wedge, having its base at the periphery, was excised sagitally from the cystic ovary. The apex of the wedge was carried down to the region of the hilum. Sutures were then passed through the ovary in such a way as to turn the cut edges of the ovary partially inside out.

In his series of seventeen cases thirteen showed a successful result by the establishment of regular menstruation immediately following the operation, and there were four failures. Most observers would agree that in the present state of our knowledge only temporary results were likely to be achieved by endocrine injections. In spite of the unscientific optimism which had replaced unreasonable scepticism with regard to endocrine treatment, he believed that it should be tried in all cases at first. When it had failed he thought that the operation of extroversion of the ovaries should be carried out, provided the patient realized that a successful result could not be guaranteed.

Proof of Ovulation

The regularity with which menstruation had followed operation in the majority of his cases strongly suggested ovulation from ovaries which certainly showed no recent or remote evidence of this at the operation. Proof of this fact, however, was not forthcoming in this series until

recently, when his third case, which had had two and a quarter years' amenorrhoea and in which there was no trace of a corpus luteum in either ovary at operation, became pregnant seven months ago. In this case regular menstruation began five weeks after operation, and continued without endocrine assistance at regular intervals of four to five weeks for two years until the advent of the present pregnancy. Ovulation, therefore, had taken place recently, and it seemed fair to assume that ovulation had occurred on other occasions since the operation. Some regular stimulus to menstruation had been present in this case (as in the other successful cases of the series) which had not been present before the operation. In his opinion this stimulus was ovulation, which could not, of course, be proved in any case unless pregnancy took place.

Dr. Bailey said that, while recognizing the inadvisability of performing a laparotomy without a thorough trial of general and endocrine treatment, he would definitely assert that this operation was justifiable both with the object of restoring normal menstruation and also improving the prospects of pregnancy, provided that all concerned were aware that a successful result could only be expected in 75 per cent. of cases.

Discussion

The PRESIDENT (Dr. Bride) said that Dr. Bailey had cleared up many of the points which were not clear in his previous communication. Mr. HARVEY EVERS (Newcastle) said that in his experience cystic ovaries were rare in secondary amenorrhoea. He mentioned a case where a whole year of endocrine therapy was necessary to produce a period. Almost at once the patient then became pregnant, and a year after the first confinement she had another baby. Dr. J. W. A. Hunter (Manchester) congratulated Dr. Bailey. He thought it disappointing that a surgical method could produce better results than endocrine treatment. He asked whether Dr. Bailey's cases were due to pituitary or to ovarian deficiency. He could not see how an ovarian operation could affect a pituitary deficiency. He asked whether any of Dr. Bailey's cases had developed dysmenorrhoea, and whether the basal metabolic rate had been taken. He thought it would be useful if such cases could be thoroughly investigated before and after the operation.

Dr. BAILEY, in reply to the president, said that the risk of the operation was small, with little bleeding at the time. He always investigated for adhesions subsequently. In his series he could feel—in most cases—cystic ovaries. The basal metabolic rate had not been estimated and examination of the endometrium had not been carried out, as all but two of this series were operated on before the publication of Kauffman's paper on the endocrine treatment of this condition. In his opinion most cases of secondary amenorrhoea were due to primary ovarian deficiency, or insensitivity of the ovary or uterus to pituitary stimuli. He agreed with Dr. Hunter about the indiscriminate application of this operation; that was why he had been sixteen months considering his cases before reading his second paper. He said that the operation should not be done except as a last resort.

Dr. WILLIAM HUNTER (Newcastle) read a short paper on two cases of rupture of the uterus and two cases of prolapse of the umbilical cord. Mr. BRYAN WILLIAMS (Liverpool) read a note on the use of prontosil in obstetrics. Mr. T. F. TODD (Manchester) discussed the relief of pain in pelvic malignancy, with special reference to the intrathecal injection of alcohol. Finally Professor FARQUHAR MURRAY read a paper on the evolution of the emergency service.

Professor Jacques Parisot of Nancy and member of the Conseil Supérieur d'Hygiène de France has been elected chairman of the Health Committee of the League of Nations in the place of Dr. Madsen of Copenhagen.

OXFORD OPHTHALMOLOGICAL CONGRESS

The Problem of Myopia

With the Master, Mr. C. G. RUSS WOOD (Oxford) in the chair, the twenty-sixth annual meeting of the Oxford Ophthalmological Congress took place on July 8 to 10 at Keble College, when a discussion on the problem of myopia was opened by Mr. N. BISHOP HARMAN and Mr. ARNOLD SORSBY.

Mr. Bishop Harman said that the myopic eye was a diseased structure, and this disease, which began in childhood, was caused and influenced by environmental factors. The school was responsible for its development in the first place, and close work later in life for the breakdown that myopes experienced. The greater incidence of myopia in girls (who did much fine work) than in boys, the effect of debilitating conditions in precipitating myopia, the significance of astigmatism as a half-way house to myopia, the greater incidence of visual defect in the poorer sections of the community, all tended to emphasize the significance of environmental factors. Evidence from Sweden showed that the introduction of an advanced system of school hygiene had reduced the incidence of myopia in that country. Mr. Bishop Harman could see little support for the theory of heredity as the determining factor in the development of myopia. In his own statistics of high myopes no family history of myopia could be obtained in 67 per cent. The incidence of the breakdown that myopes experienced in later life had a direct relation to the degree of myopia. Myopia was responsible for 3.6 per cent. of blindness in children and for a much heavier percentage in adults. The myope schools had their justification in providing for the myopic child an education from which it could benefit and which prepared it for later life.

Mr. Sorsby said that Mr. Bishop Harman's finding of a family history in 33 per cent. of his cases of high myopia was more significant than his failure to obtain such a history in 67 per cent., for it supported the view that myopia was a recessive character. The belief that myopia was caused and aggravated by environmental conditions was part of the mechanistic theories of the last century, which saw the myopic eye as an elongated structure and searched for mechanical factors to explain that elongation. Yet axial elongation as the cause of low and medium myopia had never been satisfactorily proved, and recent work by Tron seriously challenged that conception. There was no valid reason for regarding most myopia as pathological. The biomathematical approach denied the emmetropic eye as an ideal; departures from it either in the hypermetropic or myopic direction were to be regarded as biological variants. Such a conception had to face the difficulty that myopes on this distribution were in excess of the theoretical incidence. This excess was to be regarded as representing pathological myopia. The fundus lesions in myopia were not always present, even in high myopia; and the possibility of these being linked with pathological and hereditary myopia only had to be considered. That it was the pathological myope only who showed the myopic fundus changes was supported by the reports on the familial incidence of retinal detachment in myopia.

In the discussion that followed Mr. T. HENDERSON (Nottingham) argued for myopia as a stigma of constitutional weakness; Mr. WILLIAMSON-NOBLE suggested that refractive errors and eye colour tended to be inherited together; Mr. R. BEATSON HIRD (Birmingham) drew attention to adrenaline in the treatment of myopia; Mr. T. HARRISON BUTLER (Birmingham) stressed the hereditary basis of anisometropia; and Sir ARNOLD LAWSON described the symptoms of incipient progression in myopia.

Hormones and Vitamins in Ophthalmology

A paper by Sir WALTER LANGDON-BROWN on hormones and vitamins in ophthalmology critically reviewed the

present state of knowledge in these fields. Vitamin A, which was responsible for the power of the normal epithelium in withstanding infection, but had proved powerless in combating the infection itself, had now been proved a chemical organizer, for faulty development of the eyes was seen in the young of a sow deprived of vitamin A. Vitamin B_2 had been shown as responsible for a form of retrobulbar neuritis, and vitamin D played an important part in hypocalcaemia with zonular cataract. Of the ductless glands the pineal body and the pituitary had pressure effects in disease, the pituitary further influencing the eye through the thyrotropic hormone of the pars anterior, which is responsible for exophthalmos, particularly the paradoxical type seen after thyroidectomy. The ophthalmoplegia of exophthalmos was possibly also of thyrotropic origin. The adrenals played as doubtful a part in glaucoma as did the gonads in retinitis pigmentosa. A host of obscure lesions with ocular signs such as fragilitas ossium, the Laurence-Moon-Biedl syndrome, arachnodactyly, osteitis deformans, were also regarded as of endocrine origin on inconclusive evidence. The ocular lesions in diabetes were more definite, though there were difficulties in recognizing some of them clearly as diabetic. Temporary ophthalmoplegia did not seem to be so frequently seen now as in the pre-insulin days. A point of importance in the development of diabetic lesions was to recognize the change in the dietetics of diabetes that insulin had brought about.

Night Blindness

The Doyne Memorial Lecture this year, on "Night Blindness in Eye Diseases—Suggestions and Speculations," was read on behalf of the late Dr. DAVID J. WOOD (Capetown) by Dr. R. C. J. MEYER (Johannesburg), who first paid an eloquent tribute in memory of his colleague. Laying stress upon the histology of the pigment epithelium, the photo-chemical changes in the rods and cones, and the significance of vitamin A deficiency as the cause of epidemic night-blindness, the argument developed to bring out the significance of an intracellular enzyme as the initiator of the changes which lead to the building up of visual purple from vitamin A. A defect of this intracellular enzyme was to be regarded as one of the inborn errors of metabolism. It was possible that the same enzyme produced pigment pre-natally and metabolized visual purple post-natally. The reported treatment of retinitis pigmentosa by carotene, the precursor of vitamin A, was but one indication of the possibilities which must await a fuller understanding of the chemical processes involved.

Other Papers

Among other papers read at the Congress there was a profusely illustrated discourse on plastic surgery of the eyelids by Professor JOSEPH IMRE (Budapest), and an account by Dr. J. DALLOS (Budapest) on the principles underlying the fitting of contact lenses so that they could be tolerated for practically constant wear. Dr. A. J. BEDDELL (Albany, N.Y.) showed a series of highly successful colour photographs of the fundus oculi, and Mr. TUDOR THOMAS (Cardiff) described two modifications in the technique of corneal grafting, one being the discontinuance of the use of oil for the reception of the graft, and the other a new method of tying the sutures holding the graft in position.

The first *Catalogue of British Medical Films*, published by the British Film Institute and noted in these columns (February 22, 1936, p. 378) listed some four hundred films. A *Supplementary Catalogue* has now been issued in which details are given of about a hundred further films. They are classified and described under general headings, and there is in addition a subject index. The number and variety of purely medical and surgical films catalogued gives some indication of the rapid extension of this branch of cinematography within recent years.

Local News

INDIA

Proposed India League of Health

Lord Horder gave a luncheon party last week at Claridge's Hotel, London, to meet the High Commissioner for India (Sir Firoz Khan Noon) and representatives of the Councils of the People's League of Health to commend a project for the establishment of an All-India League of Health on lines analogous to the organization in Great Britain. The possibility of placing at the disposal of the people of India the knowledge gathered and co-ordinated by the People's League of Health, said Lord Horder, was first mooted in 1925, when Major-General J. B. Smith, then Medical Adviser to the Secretary of State for India, expressed the view that such a body would be of much value to the Indian Empire. The present time was felt to be an opportune one to explore the possibilities of establishing a sister body in India which might collaborate with the League in making the people of the Indian Empire "health-conscious," and thereby the better able to fulfil the duties of citizenship which were now being entrusted to them. Although the League had the sympathy and encouragement of the Minister of Health and of other Government Departments, it was a voluntary body. In a highly individualized society there existed a mass of expert knowledge, resident in trained and responsible men and women, which needed mobilizing in the interest of the community. To do this and to make this knowledge available for the people by the way of health education was the work of the League. "We venture to think that a similar body, having similar functions, may be of equal service to the people of India." Brief speeches were then made on different aspects of the work of the League by Dr. C. O. Hawthorne, its chairman of council; Dr. P. Manson-Bahr, who spoke on the triumphs of tropical medicine; Professor J. C. Drummond and Dr. Harriette Chick, who spoke on nutrition; Sir Frederick Hobday, who explained the importance of the work done by the veterinary council of the League; and Professor James Young, who described an investigation now taking place under the League's auspices on the nutrition of expectant and nursing mothers. The High Commissioner congratulated the League on having a worker like Miss Nethersole. India, he said, had reached a stage where she was able to co-operate in matters of public health and medical research with scientists in this country for the benefit of her own people. He mentioned various achievements which had already taken place, notably the elimination of cholera from the Punjab. The great difficulty was the poverty of the people. The urgency and importance of health problems was very much in the minds of the legislators; they were doing their utmost to solve them as far as finances allowed, and they would be indeed grateful for the offer of expert help which was now being made.

On the motion of Lord Horder a resolution was carried to the effect that the time had arrived when an appeal should be made to the people of India, with the sympathy of the Indian Ministries of Health and other social organizations, to co-ordinate the health work already being done in India on an all-India basis under an Indian League of Health on the lines of the People's League of Health in Great Britain. A further resolution requested the High Commissioner to convey to the authorities the offer of the People's League of Health to place at the service of India the combined knowledge of its Medical, Science, and Veterinary Councils as also its co-operation in every respect, to make the Indian League of Health a success.

The Kashmir Mission Hospital

In 1936 the Church Missionary Hospital in Kashmir received 2,383 in-patients; there were 3,976 surgical operations and the attendances totalled 39,500. Entropion and trichiasis have much decreased during recent years, probably in consequence of patients coming for treatment more readily in the early stages of trachoma. The reduced incidence in the case of this hospital is also partly explained by the greater number now of State dispensaries for these patients. There were fewer cases of kangri-burn epithelioma, and the reason given in the annual report for 1937 of this institution is that dress reform in Kashmir has led to the superseding of a loose garment resembling a night-shirt by a closer-fitting coat, waistcoat, and shirt, which prevent the krangi from being hugged close to the skin, at any rate in the daytime. Heart disease, more especially involving the mitral valve, is still common, and there are more cases of incompetence than of stenosis. Massive doses of digitalis sometimes proved to be dramatically effective. Cases of bone disease were also common, and caused difficulties of accommodation owing to the usually long in-patient treatment generally necessitated. These patients had had long periods of treatment with ointments by unqualified native practitioners, and very often sequestra had to be removed or amputation be performed. Financial difficulties, owing in some cases to temporary and non-recurring emergencies, have been considerable this last year, and Dr. E. F. Neve appeals for increased assistance for this hospital, which was one of the first in India to adopt Listerian antisepsis wholeheartedly. Situated outside the city of Srinagar, there is a great influx of poverty-stricken patients from the whole of Kashmir.

ENGLAND AND WALES

Qualifications of Coroners

The London County Council, which for many years has made a practice of appointing as coroners only persons with a double qualification, both legal and medical, has decided to fall in with the recommendation of the Departmental Committee that in future only solicitors or barristers should be appointed as coroners, but that whenever possible they should have had experience as deputy coroners. Before making a recommendation to this effect the Public Control Committee of the Council received representations from the British Medical Association against the proposal, and subsequently heard the views of deputations from the Association, the General Medical Council, the Law Society, and the General Council of the Bar. The Public Control Committee reported that in its view there was no doubt that the past practice of the Council of requiring both a legal and a medical qualification had restricted the field of candidates. In 1919, when candidates were required to possess only one or other of the prescribed qualifications, there were forty-three applications. On the basis of the dual qualification this number was reduced to twenty, fourteen, and sixteen respectively on the occurrence of the three succeeding vacancies. Apart from this, it was felt that regard must be had to the findings of the Departmental Committee in this respect, "and the representations made to us by the British Medical Association on the subject have not changed our view." Section I of the Coroners (Amendment) Act, 1926, stipulates that no person shall be qualified to be appointed a county coroner unless he is a barrister, solicitor, or legally qualified medical practitioner, of not less than five years' standing in his profession, provided that no person who has been a franchise coroner or a deputy to a county or borough coroner shall by reason of this provision be disqualified from being appointed to be a county or borough coroner. The resolution as adopted by the Council states that no person shall be eligible for appointment as coroner in the County of London unless he is a barrister or solicitor or possesses one of the qualifications required by the above section, and that in the choice of persons for such appointments due weight shall be given to experience as deputy coroners and to the possession of a knowledge of forensic medicine. It is pointed out that effect has already been given by the Council to many of the recommendations in the Departmental Committee's report. For example, with regard to the recommendation that post-mortem examinations ordered by coroners should be made by special pathologists, for many years past a panel containing the names of skilled pathologists has been kept by the Council for the use of coroners. Provision is contained in the schedule of fees made by the Council for fees not exceeding seven guineas to be paid to expert pathologists and toxicologists for special examinations in response to requests made by coroners. The schedule also makes provision for the payment of a fee of half a guinea to a medical practitioner who attended the deceased and from whom the coroner asks for a report.

The Health Congress in Birmingham

Representatives from all parts of the world have assembled in Birmingham this week for the health congress held there by the Royal Sanitary Institute. The delegates include representatives from China, Colombia, Germany, Guatemala, Iran, Liberia, Luxembourg, Rumania, Siam, and the United States of America, and from practically every British Dominion and Colony. Delegates have also been appointed by a large number of local authorities, Government Departments, and learned societies in Great Britain. The president, Lord Dudley, gave his inaugural address on Monday, and the Minister of Health, Sir Kingsley Wood, addressed a general session on Tuesday. Sir Arthur MacNalty, Chief Medical Officer of the Ministry of Health, is the president of the Preventive Medicine Section, in which the development of the maternity service has been discussed. Mr. Geoffrey Shakespeare, M.P., has addressed the Section of Maternity, Child Welfare, and School Hygiene, which discussed on Thursday the care of the pre-school child. Papers dealing with meat inspection and the protection of the milk supply have been discussed in the Veterinary Hygiene Section. In addition there are Sections on National Health Insurance, Hygiene in Industry, and Sewage Disposal, and also a Section on Tropical Hygiene for the visitors from over-seas.

West London Medico-Chirurgical Society

The fifty-fifth annual dinner of the West London Medico-Chirurgical Society was held at the Trocadero Restaurant on July 7, under the presidency of Mr. Neil Sinclair. In proposing the toast of "The Society," Sir Gervais Rentoul, K.C., pointed out that the area of his jurisdiction covered West London, and therefore his contacts with members of the Society were many. He drew an amusing distinction between the doctor, who in public was always praised, and the lawyer, who was always reviled, suggesting mildly that in private the reverse might hold. He paid a tribute to the Society for the way in which it had helped to maintain "the high standards of a very great profession." In responding to the toast, Mr. Neil Sinclair sketched briefly the progress made during the year. There was a record number of new members, the Society had moved into its new headquarters, a large number of meetings had been held, and a particularly successful Cavendish lecture had been delivered by Sir Walter Langdon-Brown. The president conveyed the thanks of the Society to the honorary secretaries, Dr. W. K. McKinstry and Mr. A. Simpson-Smith, for the work they had done. In proposing the toast of "The Guests and Kindred Societies," Mr. V. B. Green-Armytage mentioned the many distinguished medical societies represented there by their presidents, and he made a special reference to the late Sir Squire Sprigge, who, he said, was once an honoured

member of the West London Medico-Chirurgical Society. In replying, Sir Walter Langdon-Brown discussed the work of Henry Cavendish, which had been described as a triumph of the third place of decimals, particularly from the point of view of the part played by imagination in scientific medicine. Sir William Willcox, president of the Medical Society of London, who also responded on behalf of the guests, paid a further tribute to the West London Medico-Chirurgical Society, which, he said, was fortunate in having among its members so many general practitioners.

Silicosis in Miners and Quarrymen

The Medical Research Council's Committee on Pulmonary Diseases is planning a comprehensive investigation of the incidence of silicosis and other pulmonary diseases in miners. The executive council of the South Wales Miners' Federation has agreed to co-operate in the inquiry, which will involve the medical and radiological examination of a large number of men employed at selected collieries. At the same time a clinic established last year by the King Edward VII Welsh National Memorial Association is continuing work on the prevalence of silicosis and tuberculosis among the quarry workers at Blaenau Festiniog. In an interview reported in the *Manchester Guardian* Dr. J. W. Morris, medical officer of health for this area, suggested that since the adoption of rock drilling by compressed air machinery underground the number of quarrymen suffering from silicosis had substantially increased. The men engaged on this work were supplied with masks, but he thought that they did not all wear them. For reducing the prevalence of silicosis among these workers he thought that a better system of ventilation was necessary to draw the dust from the rock-face, and the wearing of masks should be made compulsory.

Health of the Port of London

On Saturday, July 10, a number of medical men were entertained by Mr. Alfred Robertson, chairman of the Port of London Health Committee of the Corporation of the City of London, on board the Port of London Authority's steam yacht *St. Katharine*. The members of the committee and guests assembled at Tower Pier and embarked at 10 a.m., and had a most interesting trip to the lower reaches of the Thames, arriving at Gravesend in time for a luncheon party on board. Dr. P. G. Stock, proposing the toast of the Lord Mayor and Corporation, said that few people realized the magnitude and efficiency of the organization of the Port of London health service. Alderman Sir John Laurie, in reply, acknowledged the support given by the Ministry of Health in this work, and said that the motto of the committee was "Deeds, not Words." Mr. Fred Whittingham expressed thanks to the Port of London Authority for its courtesy in lending the yacht for this annual inspection, and Mr. A. Binns, chief engineer, replied on behalf of the P.L.A. Mr. Alfred Robertson proposed a comprehensive toast to his guests, coupling with it the names of Mr. E. G. Culpin of the L.C.C., Sir Robert Stanton Woods, and the Mayor of Gravesend. Sir Robert expressed his admiration for the smooth running of all the work of the City Corporation, and in particular for its wonderful sanitary organization which kept the biggest port in the world free from disease. The speeches ended with a very warm tribute to Mr. Robertson from his predecessor in the chair of the Port Health Committee, who described him as essentially a practical man; and the chairman thanked Dr. C. F. White, M.O.H. for the Port of London, for all he had done to make the day's work and pleasure a success. The company then went on board the hulk *Hygeia*, from which all incoming vessels are inspected by the port medical staff, and spent an hour ashore at the isolation hospital at Denton, returning to Tower Bridge by river in the *St. Katharine*.

Testimonial to Dr. F. W. Eurich

After being in practice as a consulting physician for over thirty years and for twenty-four years professor of medical jurisprudence at Leeds University, Dr. F. W. Eurich has intimated his intention to retire from practice. The very large number of colleagues who, during the long period of Dr. Eurich's work have sought his aid in the treatment of their patients, including in many cases themselves and their relatives, wish to give some small indication of the great esteem in which he is held by all who know him. It is proposed that subscriptions, limited to one guinea, should be invited from all medical practitioners who have been associated with Dr. Eurich, and it is intended to present this token of esteem at a dinner to be held at 8 p.m. on Wednesday, September 29, at the Midland Hotel, Bradford. (Charge 10s. 6d. exclusive of wines.) Any medical practitioner wishing to subscribe to the testimonial or be present at the dinner is invited to send a remittance to Dr. F. E. Chester Williams, hon. secretary, Bradford Medico-Chirurgical Society, or Dr. Geoffrey Priestman, hon. secretary, Bradford Division, British Medical Association.

SCOTLAND

Health Problems of Edinburgh

The annual report by Dr. John Guy, medical officer of health for the city of Edinburgh, shows that the death rate in Edinburgh for 1936 was 13.4 per 1,000, an increase over the 15.3 of 1935. The report refers to the average death rate for the preceding five years. Births had numbered 7,391, or 15.9 per 1,000, which was an increase over the 15.3 of 1935. The report refers to the difficulty experienced in staffing the general municipal hospitals, which had retarded any effort to shorten the hours of duty of the existing staff. This difficulty applied particularly to the staffing of hospitals for chronic sick patients, but was a common experience of all the hospitals in the country. Attention is drawn to the fact that the actual number of females in the 20–25 years age group of the population has diminished, and this is suggested as a partial explanation of the difficulty in obtaining probationer nurses. The importance of mental examination of delinquent children is emphasized in the report, which points out that no legal provision exists for the mentally defective child under the age of 5 years, and while most of these are best treated in their own home, there is a proportion for whom some form of institutional care is imperative. Accordingly, the Public Health Committee has set aside in Gogarburn institution a block of twenty cots to which uncertified children may be admitted.

At a meeting of the Public Health Committee of Edinburgh Town Council on July 1 a proposal was made to abolish fees for treatment in the municipal general hospitals, but it was decided to continue charging those patients who were able to pay. One speaker said that while the English Act of 1929 compelled municipal hospitals to charge, in Scotland the provision was that they might charge patients. In Edinburgh they had resolved that if a patient could pay he would be expected to do so, but that the limit charge would be 25s. per week. There was a waiting list of 3,000 for the Royal Infirmary, of whom 1,000 were Edinburgh ratepayers entitled to claim admission to a municipal general hospital. The provision of a new hospital for this number of persons would add 1s. 1d. to the rates in the £1. It would, further, have the effect of hindering not of helping the voluntary hospital. The remedy, in the speaker's view, was that the spirit of the Local Government Act should be applied in the treatment of sick poor, and all admissions to

hospitals from the Public Assistance Department should be transferred to the Public Health Department, so that these people would be treated as sick persons and not as paupers.

St. Andrews University

At the graduation ceremony of St. Andrews University on June 30 thirty-four graduands received the degrees of M.B., Ch.B., and two that of M.D. The degree of LL.D. was conferred, among others, upon Angus Macgillivray, M.D., D.Sc., and Professor A. Blyth Webster, in presenting him for the degree, said that he was a graduate of Aberdeen and had been reader in ophthalmology at the University of St. Andrews, while as assessor on the University Court since 1921 he had taken a great interest in the work of the University. The principal, Sir James Irvine, in an address to the graduands, discussed the benefits for which people attended a university. He said that it was a rare privilege to be a member of a university and have the riches of learning continually spread before them. He gratefully recognized that there was little to criticize in the daily activities of the average student, but the fact could not be ignored that a change was gradually creeping over their traditional resolute character. There was a concensus of opinion that in most universities the proportion was growing of those who passed through the university with the candid intention of having "a good time." Their intention was disguised under the pretext that a university was intended as much for the development of character as for the inculcation of knowledge, and there was a danger that minority example might degenerate into a species of minority rule. He pleaded for the University of St. Andrews to take a stand in opposition to the irresponsible tendencies of the age, and call for a revival of older and sterner standards of student duty. University life must be arduous, but it could be very happy without incurring the reproach of being frivolous. The real test of a student was found not in examination results alone, but in his choice of friends and in the way he spent his hours after the work of the day was over. Even if rules could not be formulated to control the use of leisure, there remained a hope that public spirit in the universities would frown on flaunting idleness as bad form. Graduates of a university could find many opportunities to influence their successors, and the university should take a lead in making the quest for pleasure a secondary issue and not the main objective of the student's life.

Aberdeen University Graduation

At the Aberdeen University summer graduation on July 7 Lord Meston, the chancellor, who presided, conferred 201 degrees, including that of M.D. upon six graduates, Ch.M. upon one, and M.B., Ch.B. on seventy-nine. The degree of LL.D. was conferred upon Emeritus Professor Theodore Shennan, of whom the dean of the Faculty of Law said that he had been a graduate in medicine of Edinburgh and a Fellow of the Royal College of Surgeons of Edinburgh. He had come to Aberdeen to occupy the chair of pathology in 1914 equipped with a wide pathological experience gathered in the Royal Infirmary of Edinburgh, where he was senior pathologist. During his tenure of this chair he had acted as pathologist to Aberdeen Royal Infirmary, where his experience was widely sought in medico-legal matters and other questions of importance. He had rendered valuable service to the Senatus, and from 1931 had been a member of the University Court, where his contributions to the organization of the medical school, the welfare of its students, and the care of their professional interests had been of great importance. He had been specially concerned in securing to the students one free afternoon each week for sport and athletics. The University of Aberdeen was glad to honour one who had given a large part of his life to her services and added greatly to her lustre.

Correspondence

Defective Hearing and a Deaf Persons Act

SIR,—The statistical imagination is a rare gift, by using which Mr. A. G. Wells has offered an estimate of the number of persons who would come within the scope of a Deaf Persons Act on the lines of the Blind Persons Act, 1920. Unfortunately he has not been restricted by the provisions of the Act he mentions, and is equally unhampered by the purposes hitherto set out as desirable in a Deaf Persons Bill. To be scientific and accurate he should state the kind of Deaf Persons Act to which his estimates apply.

It was the long neglect of officials and politicians concerning the duty of instructing deaf children in speech at the optimum time for its acquirement, between the ages of 2 and 5 years, which prompted the main purpose of the suggested Bill; and with this was involved discovery by requirement of early registration of deafness under a penalty; and also the power of ascertainment of fitness by compelling necessary medical examination. Again, when the usual school age was passed, to prevent a costly education being wasted, the need of training in some vocational skill was suggested as a duty.

These things can all be got in time, but would come quickly if there were a Deaf Persons Act turning the attention of councils and municipalities to the neglect of the deaf. We may accept Mr. Wells's estimate as reasonably covered in all respects by 30,000 persons coming within any educational care imposed by such an Act, remembering that a great part of their needs is already met. The other purpose in the Bill was directed to the many deaf who, like the blind, easily fall out in the whirl of life. Earlier than usual they become unemployed and unemployable. Dr. Eichholz pictures them old: "entry into the workhouse means confinement to mental solitude and isolation for the rest of their lives. Neither inmate nor staff can, as a rule, understand them or extend to them even the limited amenities of social life." Here the Blind Acts make the benefits of the Old Age Pensions Acts applicable from the age of 50 years. Apart from those deaf from an early age, and already more or less under care of the Act, any cases qualifying under such provisions would be comparatively rare.

In another statistical flight Mr. Wells claims 113,000 persons over 65 years of age, and some 35,000 noisy traders for inclusion under the proposed Act, or some 70 per cent. of his gross total. Not one-fiftieth of these numbers would ever have the slightest likelihood of recognition in any Deaf Bill which would get reasonable consideration.

A Deaf Act should be got on the Statute Book as soon as possible. The estimate of those affected directly by the Act would be 30,000 at present getting incomplete educational help but requiring full recognition and educational benefits. Later in life probably about 15,000 cases, including a majority formerly included in the first category, would appear for pension help. The greatest aid, however, would be in municipal recognition of deaf welfare as a social duty, and the many ancillary trivial ways in which a community can benefit its individuals. For the benefits in these innumerable ways the cost would be very small.—I am, etc.,

Edinburgh, July 5. JAMES KERR.

The Prevention of Constipation

SIR,—I have only just read Dr. E. M. Dimock's reply (*Journal*, June 26, p. 1336) to my letter in your issue of May 29 (p. 1134). It seems to me he does not reply to my criticisms but to some imaginary contention which I have not advanced. It is true that I quoted a distinguished and independent-minded physician as stating the views to which I, an experienced but mere journeyman of medicine, also had come; but it is no answer to my contention to say that:

"The fact that such an acute observer as Dr. Hutchison has no high opinion of the dietetic treatment of constipation is probably explicable on the grounds that the patients with constipation that he sees in his consulting practice are a selected group—selected by their severity and hypochondriasis—and are not suitable material on which to form an opinion as to the treatment of the ordinary habitual constipation which is encountered in general practice."

In remote Cornwall and in East London I at least have not come into contact with "a selected group." I still see no reason to differentiate "physiologically" between the action of a seidlitz powder, which osmotically retains a sufficient bulk of water in the alimentary canal to promote peristalsis, and the action of a substance such as fibre or psyllium seed, which absorbs and retains fluid as a colloidal property. The empiric point is that in over forty years' practice I have never found patients—needing eliminative help—who have as a result of taking mild salines, such as seidlitz powders or fruit salts, experienced the unpleasant results that Dr. Dimock in his enthusiasm for bran seems to have discovered in his patients.—I am, etc.,

London, E.1, July 7. HARRY ROBERTS.

Technique in Knee-joint Operations

SIR,—As one who believes that surgical technique has made great advances since the days of Lister, I am sorry to find so eminent a surgeon as Mr. Naughton Dunn (*Journal*, July 3, p. 34) still advocating the antiquated and barbarous practice of slopping powerful chemical antiseptics into what should be clean operation wounds. Everyone knows that it is not possible to sterilize the skin by means of chemical antiseptics. But there is a considerable amount of evidence that the application of tincture of iodine or spirit to the dry skin effects at least a superficial disinfection which is of some value as a preparation for operation. It has been shown that this effect is due almost entirely to the hyperaemia and leucocytosis produced by the application. It should be noted, however, that the skin must be dry, and that washing it with soap and water or otherwise moistening it nullifies this effect. Chemical antiseptics are general protoplasmic poisons, and it is unlikely that a smear of iodine on the moist surface of a wound has any bactericidal action unless the application is so strong that it destroys all the living cells with which it comes in contact.

The fundamental principle of the Lane technique is that skin is septic, that anything which has touched skin is septic, and that anything which has touched that thing is also contaminated. The tissues deep to the skin are normally sterile, so that if access can be obtained to them without contaminating them from outside, an operation can be conducted aseptically. Skin, therefore, must be excluded from the field of operation at once, and thereafter the only things allowed to enter a wound are untouched boiled steel, sterile swabs handled with sterile forceps, and a very few ligatures and sutures, also untouched. It is true that theoretically the passage of the knife through the skin contaminates the subcutaneous tissues. But, provided that the knife is clean and sharp, this risk is practically negligible, and Lane always insisted that the cut edges of the skin should not be irritated by chemical antiseptics, which do no good and which only damage the exposed tissue cells, increase post-operative reaction, and delay healing. Some surgeons have an almost pathetic belief in the virtues of "a spot of iodine."

No reasonable person can doubt that a sterile towel is a cleaner thing to be touched by instruments entering and leaving a wound than the dirty skin of the patient, and I cannot share Mr. Dunn's fantastic notion of micro-organisms of the skin jumping through a sterile towel as soon as it is put over them. I agree that nothing can eliminate the possibility of infection, and Lane was the first to admit that there is no such thing as absolute asepsis. But there is no question that the proper use of wound towels practically excludes the principal source of infection, and no surgeon who pretends to operate aseptically can afford to ignore this elementary precaution. The Lane technique is a method of aseptic operating which has never been surpassed and rarely equalled. It is a mass of detail, each item seemingly trivial enough in itself, but as a whole giving the greatest measure of security that has yet been achieved in surgery.—I am, etc.,

London, W.1, July 6. A. S. BLUNDELL BANKART.

PS.—Since writing the above I have read Mr. Eric Lloyd's letter in the *Journal* of July 10 (p. 87), and I would like to add that it was not I but Mr. Lloyd himself who attributed his stitch abscesses to catgut. I agree that catgut can be infected in many ways. But I gave Mr. Lloyd the credit for being the careful and conscientious surgeon that I know he is. He wears gloves, he does not handle his sutures, and I presume that he uses one of the reliable brands of catgut which is sterile and not over-hardened. Was I not justified in pointing out the one obvious source of infection which he chooses deliberately to ignore?—A. S. B. B.

Treatment of Retained Placenta

SIR,—I have read with great interest Mr. David Currie's article on retained placenta (*Journal*, July 10, p. 57). Some years ago I was foolish enough to express the opinion that manual removal of the placenta was never necessary. The following week I had to do it twice. In each case it was like separating a fly-paper from the ceiling—slow, tedious, and tiring, but quite capable of competent performance.

There appear to be several statements in Mr. Currie's article to which exception might be taken. In my view placental retention is stressed when it really is of small importance. Once the placenta has separated there ought to be little difficulty in expelling it, and the idea of removing it by hand appals me. Again, what evidence is there that irregular contractions of the uterus are caused by interference? We hear constantly of meddlesome midwifery, but we hear too little of midwifery in which somebody has not meddled in time.

The intelligent use of forceps is the chief glory of the intelligent obstetrician. There is one thing above all others that must be retained—the efficiency of the uterus. Efficiency will not be retained by refusal to interfere until the uterus is exhausted. The cases Mr. Currie has seen of contraction ring following interference are due, I suggest, to bad midwifery—that is, to failure to help the powers in time. The questions to be asked at all

stages are: "Am I still clean?" and "Am I conserving the uterus?"

It is instructive to note that so much has the meddlesome bee buzzed in Mr. Currie's bonnet that a patient bled to death for want of a hand on the fundus, but estimates of the pulse rate, measurements of the blood pressure, and calculation of the amount of blood lost appear to have been a routine. There is no need to be afraid of Credé's method, nor need to be surprised that it has yielded better results in the hands of the general practitioner, who constantly gets results comparable with those of any hospital.

I cannot understand the logic of refusing to put a hand on the fundus because it is meddling, and squirting large quantities of saline up the umbilical cord because it is scientific. If the country really wants to improve on the already excellent mortality rate let it see to it that the profession eliminates its few known black sheep and put midwifery into the hands of general practitioners who have had their tonsils out.—I am, etc.,

London, N.W.4, July 12. R. W. COCKSHUT, M.B.

Cancer of the Oesophagus

SIR,—Mr. Herbert Tilley's communication on the treatment of carcinoma of the oesophagus in the mid-thoracic region by deep *x*-ray therapy (*Journal*, June 12, p. 1199), and Mr. Steele's comments on this (June 26, p. 1338), raise many points of interest for the practising surgeon who is concerned primarily with the treatment of the individual patient. Experience of these cases has convinced me that the main obstacle to the institution of early treatment is the prevalent conviction among practitioners that no available treatment really relieves the patient's symptoms, so that the patient is not sent to hospital until the need for a gastrostomy is imminent.

The purpose of this communication is to urge that all patients with dysphagia, even intermittent, should have an oesophagoscopy as well as a barium swallow as soon as their symptoms lead them to consult a doctor. That an oesophagoscopy is essential is illustrated by one of my patients, a woman of 52, who had a normal *x*-ray appearance of her oesophagus when first seen at the medical out-patient department four months after the onset of symptoms, but when an oesophagoscopy was performed two months later a large fungating growth bleeding profusely on manipulation was discovered in the middle third of the oesophagus. It is difficult to believe that oesophagoscopy would not have revealed some abnormality earlier.

Mr. Steele states his conviction that severe malaise is a usual concomitant of deep *x*-ray treatment. This is not the general experience where modern methods by long narrow fields geometrically placed are employed daily over a period of about four weeks: indeed, Mrs. Hilton has been able to treat two of my patients as out-patients without any serious general disturbance, one patient making an hour's journey each way daily, and the other being an old lady of 76 who refused any treatment which involved entrance into a nursing home or hospital.

I have had five patients with carcinoma of the mid-thoracic region (which Dr. Levitt finds less favourable than the upper third area) treated by Mrs. Hilton in the radiotherapy department of University College Hospital during the last three and a half years. All have had swallowing restored; three, treated respectively over three years, eleven months, and seven months ago, are eating normal food normally; one, who required a gastrostomy before treatment was begun, was able to swallow comfortably for five or six months until she died; while the fifth, who was bed-ridden with arthritis, was able to swallow sufficiently to prevent the necessity for a gastrostomy, which had seemed urgently called for when treatment was begun.

If practitioners could be assured that patients with carcinoma of the oesophagus when treated by *x*-ray therapy by the exact methods elaborated by Finzi and Levitt can have the power of swallowing restored, at any rate for a time, without much constitutional disturbance, patients would be sent for diagnosis and treatment at an earlier stage; and the modest claim of Mr. Tilley and Mrs. Hilton that there is now a little more hope in the treatment of this hitherto fatal disease will have an opportunity for greater fulfilment.—I am, etc.,

London, W.1, July 11. D. J. COLLIER, F.R.C.S.

Ionization for Hay Fever

SIR,—Much has been said and written about hay fever treatment, but we should not forget that the general psychological state of the patient is a big factor. It appears to be much more prevalent now than it was before the war even. Is this due to the stress of modern life, or is it due to the continuous irritation of the mucous membrane by the fumes of the modern atmosphere? Doubtless there is a big element of nervous instability, but desensitization of the nasal mucosa will damp the fuse.

It is advisable in ionization of the nasal mucosa to let the patient hold the applicators in her nose so that she can remove them at will rather than run the risk of a panic, with consequent damage in using a headband.—I am, etc.,

London, W.1, July 5. C. HAMBLEN-THOMAS.

SIR,—The excellent letter from Dr. Adam on this subject induces me to write a further short note. My results of treatment for this year are not yet complete, but the percentage of successes are not as good as last year. Three cases showed no improvement, and it is interesting to note that in each of these the hay fever was combined with asthma. I regard this combination as giving a bad prognosis for cure. I wonder if others have had this experience? Perhaps Mr. Vlasto had the bad luck to get this combination in most of his cases. I have given calcium gluconate to all my cases this year. This rather obscures the issue, but the cure of the patient must be our first concern. The gluconate is the best form of calcium—far better than the lactate—in allergic conditions.—I am, etc.,

Guildford, July 11. T. B. JOBSON.

Benzedrine and Belladonna for Hay Fever

SIR,—I have suffered from severe hay fever for ten years. Last year I had a course of zinc ionization which merely exaggerated my symptoms, and in previous years I have tried "pollacine" without any effect. There seems to be quite a large class of persons whom it is impossible to desensitize by such injections.

This year I obtained great relief with benzedrine and belladonna. On rising in the morning I took 10 minims of tincture of belladonna in half a tumbler of water and 10 milligrammes of benzedrine. This kept me free from symptoms for the greater part of the day. I have tried both these drugs separately and find them much more efficacious when used together, although the tendency for the pupils to dilate seems greater than when belladonna is used alone. In many cases the above is too large a dose, causing an unpleasant dryness of the throat and a feeling of nervous excitement, and 5 milligrammes of

benzedrine and 7 minims of tincture of belladonna are sufficient. All unpleasant symptoms can be prevented by reducing the dose.

This treatment is not claimed as a cure, for the symptoms generally return in the evening. I have tried it on several friends, all of whom obtained great relief. A useful adjunct for very bad cases is the "benzedrine inhaler," but this alone did very little good in my case. I have only tried this treatment in a few instances, so naturally my remarks about it are tentative.—I am, etc.,

Eastbourne, July 6. R. B. HEISCH.

The One-eyed Motorist and Pilot

SIR,—One-eyed pilots who flew before a certain date somewhere in 1919 can, I understand, get an A licence but they cannot get B licences.

It is possible that one in seventy of our population have useful sight in one eye only—say, 700,000 persons. They are one-eyed and for the purposes of this letter let us consider many of them blind in one eye. They live normal lives; they walk, cycle, hunt, and drive cars; they shoot; and often do not know they are blind in one eye. Indeed some who have the defect pointed out, even proved, state they do not believe it. They think their medical advisers have been mistaken. On this point some are so emphatic that they are indeed mentally blind. What I want to know is, What are the reasons which permit them to do so much that they want except fly in the air? There are no special reasons except one—that in the very rare event of sudden loss of sight in the remaining eye they must "crash land." Even this reason could be overcome by a parachute drop. In any case they should be permitted to take this risk. This same risk is taken by one-eyed motorists, hikers, mountaineers, and it is taken in lesser degree but greater quantity by two-eyed pilots. How can we live without risk? A young patient told me this week that the increasing casualty lists in the air increased his determination to join the Air Force and made it all the more attractive to him.

Remember it is not a question of the Air Force or air services, but only that of the private flyer, flying for pleasure or to help him in his work. Flying is, after all, only motoring without the road risks. One of my two-eyed friends tells me he reads a book in his Hornet Moth when flying long distances. How little the two-eyed pilot gains when flying blind (not mentally blind)!

I therefore merely ask that one-eyed individuals should be allowed the same privileges in the air that they possess on the ground. If they are allowed to drive cars, then they should be allowed to fly. If thought desirable a higher standard of vision in the single eye might be determined upon at first or for a trial period. I entirely agree with a flying instructor who tells me that a one-eyed pilot in a cabin machine is safer than a two-eyed pilot in most types of goggles.

It intrigued me to find the other day that a certified blind person whom I found to be genuinely blind within the Blind Persons Act had been drawing blind pension for ten years, and all that time he had held a driving licence! He drives a car, rides a bicycle, and has had no accident. The case was brought to my notice by a man who had been his passenger on a journey to fetch his blind pension money. In any case he told me himself that he was too blind to read the regulations in the fine print in which they are typed! He had only one eye, but could read the number plate at 25 yards with a pocket telescopic spectacle, which of course contracted his field of vision. For it must not be forgotten that persons with really bad sight and defective fields of vision and colour blindness are allowed to drive cars if they can pass the driving tests. A normal-sighted one-eyed motorist should be safer therefore than many of these individuals.

Let us here examine the position of motorists in greater detail. We find it most extraordinary. Persons who can see 6/18 (for example, a standard number plate on a car at twenty-five yards in average illumination) may drive a car, although they may have contracted fields of vision and perhaps colour blindness. Those holding licences before 1935 need not pass a driving test; thus persons eligible for blind pension may drive a car (see Group 3 below). Any persons with 6/18 vision and contracted fields would probably not pass the test, but if they become so blind at any period after the test they may continue to drive.

Roughly the blind may be divided into three groups:

1. Those with less than 3/60 vision with glasses.
2. Those with vision between 3/60 and 6/60 with glasses, when other conditions of an intricate nature, some of great complexity, are present.
3. Those with vision up to 6/6 with glasses, with fields of vision contracted to around 10 per cent. of the fixation point.

Now Group 3 is a large one, and there must be many of these persons about. Glaucoma, which is a disease with contracted fields as an essential factor, accounts for about 10 per cent. of the blind. Other common conditions with contracted fields which might account for another 10 per cent. are optic atrophy, retinitis pigmentosa, and corrected high myopia and cataract cases that have had their operations completed satisfactorily. If, therefore, this is permitted surely the one-eyed pilots with good sight have a strong case, and I should like to see them press their claims for A licences.

Standards for One-eyed A Licence Pilots

Group	Good Eye	Other Eye
(1)	6/6 vision or 100 per cent., without glasses	Blind Standard or Group 1 / Group 2 / Group 3
	Normal field of vision	
	Not colour blind	
(2)	6/9 or 90 per cent., without glasses	6/60 to 6/24 (with or without glasses)
	Normal field	Field good
	Not colour blind	
(3)	6/6 or 100 per cent., without glasses	6/24 with correction
	Normal field	Field good
	Normal colour vision	Binocular vision

Putting one-eyed A licence pilots in the air would decrease road risks, and would make other pilots more careful! It would promote aviation and its welfare (more private landing-grounds, etc.) and it would please the one-eyed individuals. It is not so much the question of "one eye *versus* intelligence" as the unintelligent pilot soon "liquidates" himself, whether he has one eye or two. There are many instances of well-known one-eyed pilots, but it is difficult to name the living ones. Wiley Post, for instance, Hinchliffe, and no doubt many others.

As I have stressed before, the difficulty of operating any standard is no easier whatever that standard may be. Revision of standards is constantly going on, but a certain amount of agitation with concrete proposals is always necessary to bring these changes about. I therefore append new standards for one-eyed A licence pilots

which I consider would meet the case, and I trust will prove acceptable. In any case it is a serious attempt to be of use in the matter.

Even in Group 3 it will be noticed that while the bad eye is below present standard required the good eye is above present necessary standard, and colour vision and fields are normal. There will always be difficult and confusing borderlines, and they could be settled by appeal as at present. This standard is not as simple as the present one, but it would be workable *at a price* which the one-eyed would be happy to pay. Somewhat similar standards if enforced for motorists would be of considerable safety value, but would prevent large numbers of motorists from driving.

If anyone, ophthalmologist or other, can see any mistakes or loopholes in this letter I should be very glad to have them pointed out.—I am, etc.,

London, W.1, June 29. J. MYLES BICKERTON, F.R.C.S.

An Obscure Case of B. coli Peritonitis

SIR,—I was much interested to read about Messrs. Wise and Gabriel's case (*Journal*, July 3, p. 34). I think one must blame the appendix as the *fons et origo* because it contained offensive pus and threadworms at the first operation. Threadworm acute appendicitis is often associated with odourless purulent fluid in the peritoneal cavity without any signs of inflammation on the outside of the appendix; in these cases infection is probably direct but blood stream infection cannot be excluded owing to the occurrence of such diseases as *B. coli* meningitis. Only a few weeks ago I removed an appendix full of threadworms and foul pus with very little peritoneal change, yet there was a large amount of odourless pus, containing pneumococci, in the peritoneal cavity. A pneumococcal empyema later delayed recovery, so there was no doubt about a blood stream infection in this case.

Having assumed that peritoneal infection could have occurred, the other difficulty is the latent period of one week; this, however, is not very unusual in post-operative peritonitis. I can recall the sudden development of signs of peritonitis 10 days after an operation for strangulated hernia, while the post-mortem examination revealed no pathology of the intestine.—I am, etc.,

Liverpool, July 5. M. J. BENNETT-JONES.

Foot-and-mouth Disease in a Man

SIR,—The following case may be worth placing on record.

In April, 1937, an auctioneer aged 24 consulted me casually for a "sore mouth." There was slight gingivitis, and there were three small bullae the size of split peas in the buccal cavity; the temperature was normal. The following day the bullae, which had become larger, were punctured by the teeth, and two fresh ones appeared; the temperature was 99.2° F. Next day there were numerous bullae and painful ulcers, and the temperature was 100.2° F.; but constitutional symptoms were surprisingly slight considering the filthy appearance of the mouth. The case was transferred to hospital, where the diagnosis of foot-and-mouth disease was confirmed. The Ministry of Agriculture were assisted in their investigations by Professor J. A. Nixon of Bristol, but up to date no trace of the infected cattle has been found.

Comparison with a case reported ten years ago is interesting. The daughter of a local farmer had only slight signs in the mouth, but there were extensive lesions of the hands; examination of the cattle in the yard brought to light early "limping" and "slobbering," and the diagnosis in three of the beasts was soon confirmed by the Ministry officials, and an extensive epidemic efficiently controlled.

A remarkable coincidence is that the late Dr. W. T. Briscoe described a local case of "human" foot-and-mouth disease over thirty years ago. I am convinced that the co-operation of the veterinary surgeons would bring to light many more cases and assist in preventing a financially serious loss to the farming community.—I am, etc.,

Chippenham, Wilts, June 17. J. HOBART NIXON, M.D.

Tests for Renal Function

SIR,—The interesting paper by Dr. C. S. D. Don in the *Journal* of July 10 (p. 54) shows a comparison of the tests for renal function and their variations. That the maximum specific gravity should be normal in certain cases of uraemia and that the phenolphthalein test should in many cases show a loss of renal function before the urea clearance test are examples. Dr. Don remarks that this failure of the tests to agree closely suggests either that they are not altogether reliable or that different renal functions are being measured.

Whether or not the tests measure different functions is a very difficult problem, although some believe they do—for example, impairment of concentrating ability showing tubular failure. I may be able, however, to mention a feature of the phenolphthalein test which must be taken into account. In a paper I contributed to the *Journal* on this test (September 29, 1917, p. 414) it was stated that Kendall had made experiments showing that want of oxygen caused destruction of the dye by the reducing substances, and also that certain cardiac diseases caused a fall in its excretion. These factors may be present in Bright's disease. It was also mentioned that in "trench" nephritis a patient with slight albuminuria but with no casts may give only an excretion of 20 per cent. in the first hour, whereas a case the urine of which is loaded with albumin and containing numerous casts may give a 50 per cent. excretion. This shows a selective action on the part of the dye.—I am, etc.,

London, W.1, July 10. A. G. AULD.

Air Raid Precautions

SIR,—One is glad to read such a sane and refreshing letter as that of Mr. Ian Fraser's in the *Journal* of July 10 (p. 90). It is an admirable review of the present position, and the suggestion of a medical committee of inquiry is an excellent one. The same cannot be said of Dr. McClean's exclusively political effort.

When I took a course of gas lectures I was not aware that I was acting as the tool of any government. I was merely trying to make myself of more use to my fellow men. I am sure that no one, in the Government or out of it, would suggest that there is any panacea against the effects of air raids, or that their prevention can be, at best, anything but a very difficult business; but that is not to say that we should give up trying unremittingly. If we can only save or relieve a small proportion of those exposed, our efforts will not have been in vain. To talk of air raid precaution schemes as being "propaganda designed to keep up the war spirit of the general population" sounds to me like utter claptrap. The war spirit simply does not exist in this country. The majority of us know only too well the horrors of war, and many of us those of gas also. What we ask is that our rulers shall arrange for us all the protection and security that is humanly possible, so that we can go peacefully about our avocations.

I admit that competitive rearmament is deplorable. But what are we to do? We were the last to come in. Others set the pace, and we perforce had to follow suit. That is the way of competition, but it is an unescapable accompaniment of the age-old principle, "Get on or get out." This applies especially to our country. We are a rich, ripe plum ready to be plucked, and our competitors will not scruple to do the necessary if we leave the orchard unprotected. In any case, Sir, cannot we stick to our briefs, and cease to "prostitute" the columns of the *Journal* with the discussion of high politics? It is a waste of valuable space in a scientific publication, and such matters should be confined to the lay press.—I am, etc.,

Shrewsbury, July 10. R. L. E. DOWNER.

SIR,—Yes, by all means let us accept Dr. W. Colquhoun's suggestion (June 26, p. 1339), and have a medical committee to "go fully into the measures adopted by the Government to protect the public." Obviously they will find, as Dr. Ian Fraser points out (July 10, p. 90), that the Government has made "no great claims at all" in this direction, and this will give the committee an opportunity themselves to make some proposals based on medical experience and knowledge. At present the Government is prepared, or is preparing, to give us all gas masks which have been proved "a protection for all known non-blistering gases," and also protective clothing against gases of the blistering kind. Against incendiary bombs it is suggested (I still quote Dr. Fraser) that "in the hour of danger" we should lay "a layer of sand on the floor of the upper rooms of our house." Finally, against high explosives, "no claims are made by the Government . . at all"; "diffusion and scattering of the population . . is all that is advised."

The Government clearly furnishes some suggestions—and with its usual generosity is prepared to expend unlimited funds—for the mitigation of casualties in the event of world war, but just as clearly it does not for one moment undertake to protect the people in anything that could be called an "adequate" fashion. Our Government, like all others, is mainly out to prevent war and this it, and they, propose to do by trying to win the armaments race.

We must not suppose, however, that the Government has no intelligence at all. It realizes—or at least its individual members do—as anyone with an elementary knowledge of human nature would, that world war with full use of modern methods of destruction would mean universal panic and chaos, at least in the big cities, and that this would be something which even the most highly qualified psychotherapeutic experts, backed by the police—or the police backed by the psychotherapeutic experts—would be entirely powerless to stem. Even the knowledge that people in other European cities were being bombed as well would do nothing to reassure the despairing and half-demented victims. In fact, the generalization may safely be made that if general war arrives the danger in the different districts will vary directly with the density of population. In other words, not merely from the point of view of danger to life and limb, but from that of starvation also, the Londoner will be in the worst position and the Hebridean crofter in the best.

If therefore an unbiased medical committee can be got together—and there is not a moment to lose—I would venture to suggest that one of the first items of their deliberations should be the following. Seeing that, in the event of world war, all the three kinds of bombs are certainly going to be used, and simultaneously, on the cities, had not the city dwellers better be preparing at once for the worst possibility? Had not "diffusion and scattering of the population," as hinted by the Government experts themselves, better begin now, when it can be done in something like decency and order, and not be delayed until hostilities open, when it will resolve itself into general pandemonium and a panic rush from the towns? As one who all his professional life has been pointing out that the increasing urban centralization of our times was going to lead civilization to disaster, I may end at this point by requoting the old adage, *Naturam expellas furca, tamen usque recurret*—which means that with whatever violence we attempt to drive Nature away she will always get her own back in the long run. It is "contrary to Nature" for the bulk of the population to be herded together into cities, and Nature will not be mocked in vain.

I trust that the main finding of the proposed medical committee will be that there is now nothing for it but advocacy of a general "diffusion and scattering of the population"—in fact, of a speedy return to the land—and that in this case we shall have no minority recommendations.—I am, etc.,

North Queensferry, Fife, July 10. A. J. BROCK.

An Echo of Culloden

SIR,—Sir Arthur MacNalty, in his most interesting lecture at the National Temperance Hospital on June 24, reported in the *Journal* of July 3, refers to Dr. Archibald Cameron as "one of the most unfortunate of medical plotters." You may remember that ten years ago there was some correspondence in your columns on Dr. Cameron. I had delivered a lecture to the Brighton and Sussex Medico-Chirurgical Society on "Some Famous Medical Criminals," and in that lecture I referred to Dr. Archibald Cameron. This was reported in the *British Medical Journal* of December 4, 1926, and was followed by a strong protest from "Nomadic Doctor" against including Dr. Cameron in such a list. I at once saw I was wrong, for Dr. Cameron was a man of the very highest character. He was medical officer in charge of troops during the rebellion of 1745. He freely gave his services to the wounded of both sides, and many Hanoverians gave testimony to his humanity to them. After the Battle of Culloden he escaped to France. Most of the rebels were pardoned, but an Act of Attainder was passed excluding certain people, including Dr. Cameron. Eight years later he returned to Scotland where he was arrested, and he was hanged in London in 1753. Many even of the Hanoverians regarded his execution as judicial murder.

I received from the late Sir Dawson Williams, Editor then of our *Journal*, one of his delightful and characteristic letters from which I quote the following: "Here you are again making trouble—not this time with a much harassed Editor, but with an irate Highlander who in the eighteenth century would probably have called upon you with his claymore freshly sharpened. We have drafted an editorial note which in this century might perhaps save you."—I am, etc.,

Hove, July 9. L. A. PARRY.

"The Medical Directory"

SIR,—To maintain the accuracy of our annual volume we rely upon the return of our schedule, which has been posted to each member of the medical profession. Should the schedule have been lost or mislaid we will gladly forward a duplicate upon request. The full names of the doctor should be sent for identification.—We are, etc.,

J. AND A. CHURCHILL, LTD.,

Obituary

JOHN TENNANT, M.D., F.R.C.S.ED.

Late Surgeon, Ulster Hospital for Women and Children

Dr. John Tennant died at Stamford, Lincolnshire, on June 23, aged 69. He came of an old and distinguished Ayrshire family, and from his early youth showed evidence of very great ability. Dux of Ayr Academy, he entered the Faculty of Arts in Edinburgh University at the early age of 17, and in his first year won the first medal and the Scott and Dunbar prize for senior Greek, and a medal for Latin. He graduated M.A. with first-class honours in classics, and then entered upon the study of medicine. During his medical course, which he completed in four years, he won many distinctions, graduating with honours in 1893. After a long spell of hospital training he settled in Belfast, where he acted as demonstrator of anatomy with Professor Symington and also gave valuable assistance to Professor Lorrain Smith in connexion with a severe outbreak of typhoid in the city. Later he specialized in gynaecology and became surgeon to the Ulster Hospital for Diseases of Women and Children.

Somewhat disappointed with his prospects in Belfast, Tennant gave up his work there and went into practice in England, first in Lincolnshire and later at St. Annes-on-Sea. As a general practitioner he was devoted to his work; his training, ability, and fine character brought him great success, and he was much beloved by his patients for his skill, his kindly sympathy, and the careful attention he gave them. He was naturally of a modest, retiring disposition, and shunned the limelight. In company he revealed a quiet genial humour, never airing his erudition, but often a half-humorous remark of his would throw fresh light on a controversial subject. He was sensitive, and disliked any coarseness of speech or rudeness in any form. I can best compare him with Chaucer's ideal of a fine gentleman:

> "He never yet no vileinye ne sayde
> In all his life unto no maner wight;
> He was a veriay perfight gentil knight."

Dr. Tennant retired from work in 1922 and returned to Belfast, his wife's native city, where he had many friends. He resumed his classical studies with great zest, and up to the time of his last illness was absorbed in the minute study of the Greek used in the Homeric poems. He was never a bookworm. He loved outdoor sports and was expert at any game he took up, such as tennis in his youth and bowls in his later years. He had been a member of the British Medical Association for forty-two years.

J. V. P.

THOMAS GILLISON, M.B., C.M.

A cable message from China records the death on June 22 of one of the oldest and most beloved of Scottish medical missionaries in the person of Thomas Gillison, who passed away at Hankow at the age of 78, after fifty-five years of devoted and unselfish labour.

Born in Baldernock in 1859, the son of a Presbyterian minister, Thomas Gillison was educated at Merchiston Castle School and Edinburgh University, and worked as a student at the famous Cowgate Dispensary of the Edinburgh Medical Mission, in company with Christie, Duncan Main, Cousland, Edwards, the Neve brothers, and others whose names are famous in medical mission history. He sailed for China in 1882 under the London Missionary Society and was appointed to Hankow, where, eleven years later, he married Dr. Elizabeth May Harris, then in charge of the Hankow Women's Mission Hospital. From that time until their recent passing away within but a few months of one another, their whole life was devoted to the service of the suffering Chinese in Central China, where the names of Dr. and Mrs. Gillison will always remain enshrined.

In 1902 Dr. Gillison, in association with Dr. P. L. McAll, founded the Hankow Union Medical College, where he not only did valuable work in training students but also translated a number of important medical text-books into Chinese, including Luff's *Chemistry* and Cunningham's *Practical Anatomy*. In 1918 the Hankow Medical College was transferred to Tsinan, to form part of the medical department of Cheeloo University. Gillison accompanied his students to Tsinan and remained there for four years, continuing his translation work and helping in the work of the medical school. The influence of his personality, and, in particular, his simplicity and rugged sincerity, made him an invaluable colleague, but his heart was always among the sick poor, and in 1922 he returned to Central China to give his services once more to the Hankow Hospital, the men's section of which now bears his name. In 1930 he retired, but the following year saw him back in China once again, and there he remained until his death, translating further books, sharing in the work of the Church, and assisting Mrs. Gillison in the conduct of a very successful dispensary. At Hankow he was joined by his eldest son and daughter—surgeon and nurse respectively—who are proving worthy successors to their parents. Dr. Gillison was decorated by the Chinese Government with the Order of the Golden Grain.

Dr. Harold Balme, former dean of the School of Medicine, Cheeloo University, writes:
